# **MATLAB API**

# sirtExplorer

Open Simulink Real-Time explorer and interact with target computers and real-time applications

# **Syntax**

slrtExplorer

# **Description**

slrtExplorer opens the Simulink Real-Time explorer.

Simulink Real-Time explorer provides a UI for viewing connection status and interacting with a real-time application. You can:

- View a hierarchical display of signals.
- Tune parameters.
- Stream data to the Simulation Data Inspector.

# **Examples**

### **Select Signals and Stream Data**

The explorer provides a view of signals in the real-time application. From this view, you can select signals to stream to the Simulation Data Inspector and visualize the data..

Open the Simulink Real-Time explorer. Type:

slrtExplorer

To connect to the selected target computer, click **Connect**.

To select and load a real-time application, click **Load Application** and select the mldatx file.

To select signals for streaming, click the application name, select signals from the **Signals** tab, and click the **Add selected signals** button.

To run the application and generate data for streaming, click the **Run** button.

To stream the signal data, select the signals in the **Group signals to stream for SDI** list and click the **Stream Signal Group to SDI** button.

To view the streaming signals, click the **Open in SDI** button.

After viewing the data, to stop the real-time application, click the **Stop** button.

**Topics Simulink Real-Time Explorer** 

# sIrtLogViewer

Open Simulink Real-Time System Log Viewer tab in Simulink Real-Time Explorer to view the console log from target computer

# **Syntax**

slrtLogViewer

# **Description**

slrtLogViewer opens Simulink Real-Time Explorer and shows the System Log Viewer tab.

# **Examples**

### **Open System Log Viewer**

Open Simulink Real-Time Explorer and show the System Log Viewer tab.

slrtLogViewer

### Topics

**Simulink Real-Time Explorer** 

# sIrtTETMonitor

Open Simulink Real-Time task execution time (TET) monitor

# Syntax

slrtTETMonitor

# **Description**

slrtTETMonitor opens the Simulink Real-Time task execution time (TET) monitor in the MATLAB session that is available for all Simulink Real-Time target objects. You can open the TET monitor at any time. Depending on the current state of connected target computers, the monitor displays TET data for each real-time application task. Changes to the target computer state are updated in the TET monitor. The monitor displays these target states:

- target\_name Waiting for real-time execution to start: Displays name of target computer
  connected to Simulink Real-Time. Displays no TET data is because no real-time application is
  loaded or executing.
- target\_name BaseRate rate\_value: Displays TET data for execution of the real-time because a real-time application is executing.

# **Examples**

### **Open TET Monitor and View Status**

In the "Data Logging with Simulation Data Inspector (SDI)" example, use these additional steps to display the TET monitor.

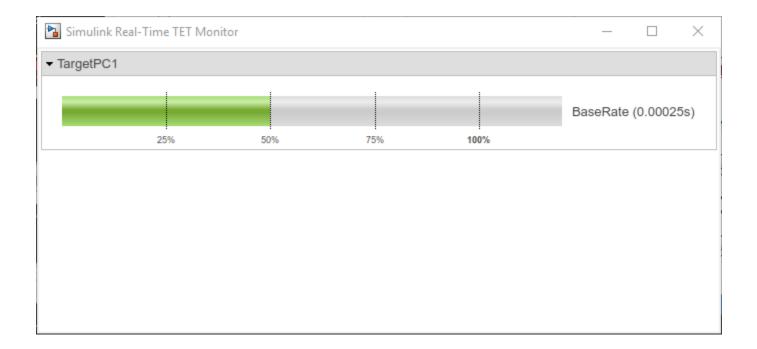

Open the slrt ex osc model.

Build the real-time application, load it on the target computer, and start the application. In Simulink Editor **Real-Time** tab, click **Run on Target**.

Open the TET monitor. In the **Real-Time** tab, click **TET Monitor**. Or, in the Command Window, enter:

slrtTETMonitor

When you run the real-time application, the TET monitor displays status.

### **View TET Data in Simulation Data Inspector**

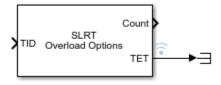

In the "Data Logging with Simulation Data Inspector (SDI)" example, use these additional steps to display the TET data in the Simulation Data Inspector.

Open the slrt ex osc model.

Add a SLRT Overload Options block to the model.

In the block, set the **Enable TET Output** parameter value to on.

Select the TET output and mark it for data logging in the Simulation Data Inspector.

Build the real-time application, load it on the target computer, and start the application. In Simulink Editor **Real-Time** tab, click **Run on Target**.

Open the Simulation Data Inspector.

When you run the real-time application, the TET data is displayed in the Simulation Data Inspector.

# **Target**

Represent real-time application and target computer status

# **Description**

A Target object represents a target computer and provides access to methods and properties related to the target computer.

The object provides access to methods and properties that:

- Start and stop the real-time application.
- Read and set parameters.
- · Monitor signals.
- Retrieve status information about the target computer.
- Restart the target computer.
- Load the real-time application.
- Start, stop, and retrieve information from the profiler.

Function names are case-sensitive. Type the entire name. Property names are not case-sensitive. You do not need to type the entire name if the characters you type are unique for the property.

You can invoke some of the object properties and functions from the target computer command line when the real-time application has been loaded. For more information, see "Target Computer Command-Line Interface".

# Creation

target\_object = slrealtime constructs a target object representing the default target
computer.

target\_object = slrealtime(target\_name) constructs a target object representing the target computer designated by target\_name.

The slrealtime function accepts these arguments:

- target\_name Name assigned to target computer (character vector or string scalar). For example, 'TargetPC1'.
- target object Object representing target computer. For example, tg.

**Example:** "Create Target Object for Default Target Computer" on page 1-11

**Example:** "Build and Run Real-Time Application" on page 1-12

# **Target Object Properties**

### TargetSettings — Target computer configuration information

TargetSettings struct

The TargetSettings property holds a TargetSettings structure that includes fields name, address, sshPort, xcpPort, username, userPassword, and rootPassword. To view the targetSettings, in the MATLAB Command Window, type

# ${\tt tg.TargetSettings}$

### ProfilerStatus — Target computer execution profiler information

Ready | StartRequested | Running | DataAvailable

The ProfilerStatus property holds the execution profiler status. To view the ProfilerStatus, in the MATLAB Command Window, type

```
tg.ProfilerStatus
ans =
   'Ready'
```

### SDIRunId — Target computer SDI run identifier

int32

The SDIRunId property holds the Simulation Data Inspector run identifier for the current simulation run. To view the SDIRunId, in the MATLAB Command Window, type

```
tg.SDIRunId
```

```
ans =
int32
22110
```

### ptpd — Target computer PTP daemon configuration

PTPControl struct

The ptpd property holds a PTPControl structure that includes fields Command and AutoStart. For more information, see the Target.ptpd object. To view the targetSettings, in the MATLAB Command Window, type

```
tg.ptpd
```

```
ans =
  PTPControl with properties:
        Command: 'ptpd -L -K -g'
        AutoStart: 1
```

### FileLog — Target computer file logger status information

FileLogger struct

The FileLog property holds a FileLogger structure that includes fields Importing, ImportProgress, LoggingService, and DataAvailable. For more information, see the Target.FileLog object. To view the targetSettings, in the MATLAB Command Window, type

### **Events**

A number of the Target object functions produce event status. You can use the MATLAB listener function to monitor event states.

- Connecting, ConnectFailed, Connected Events related to target computer connection operation by using the Real-Time tab in the Simulink Editor, Simulink Real-Time Explorer, or the connect function.
- Disconnecting, Disconnected Events related to target computer disconnection operation by using the Real-Time tab in the Simulink Editor, Simulink Real-Time Explorer, or the disconnect function.
- Installing, InstallFailed, Installed Events related to real-time application installation on a target computer by using the install function.
- Loading, LoadFailed, Loaded Events related to real-time application load on a target computer by using the Real-Time tab in the Simulink Editor, Simulink Real-Time Explorer, or the load function.
- Starting, StartFailed, Started Events related to real-time application start on a target computer by using the Real-Time tab in the Simulink Editor, Simulink Real-Time Explorer, or the start function.
- Stopping, StopFailed, Stopped Events related to real-time application stop on a target computer by using the Real-Time tab in the Simulink Editor, Simulink Real-Time Explorer, or the stop function.
- Rebooting, RebootFailed, RebootIssued Events related to target computer reboot operation by using the Simulink Real-Time Explorer or the reboot function.
- UpdateBegin, UpdateMessage, UpdateFailed, UpdateCompleted Events related to target computer RTOS software update operation by using the Simulink Real-Time Explorer or the update function.

- SetIPAddressBegin, SetIPAddressFailed, SetIPAddressCompleted Events related to target computer IP address change operation by using the Simulink Real-Time Explorer or the setipaddr function.
- StartupAppChanged Event related to target computer startup application change operation by using the Simulink Real-Time Explorer or the setStartupApp or clearStartupApp functions.
- StopTimeChanged Event related to real-time application stop time change operation by using the Simulink Real-Time Explorer or the setStopTime function.

## **Object Functions**

addInstrument Add instrument object to target object

clearStartupApp Clear startup application selection on target computer

connect Connect MATLAB to target computer

deleteProfilerData Delete execution profiler data from target computer

disconnect Disconnect MATLAB from target computer

getAvailableProfile Get information about available execution profiler data

getProfilerData Retrieve profile data object

getStartupApp Get information about startup application configuration on target computer

getparam Read value of observable parameter in real-time application

install Install real-time application on target computer

load Deploy to target and load real-time application to target computer

reboot Restart target computer

removeAllInstruments Remove instrument objects from target object

removeInstrument Remove selected instrument object from target object

resetProfiler Reset profiling service state to Ready

setipaddr Set IP address and netmask on the target computer

setStartupApp Configure startup real-time application for target computer

setStopTime Configure stop time for real-time application

setparam Change value of tunable parameter in real-time application start Start execution of real-time application on target computer

startProfiler Start profiling service on target computer

status Get status of real-time application on target computer stop Stop execution of real-time application on target computer

stopProfiler Stop profiling service on target computer update Update RTOS version on target computer

# **Examples**

### **Create Target Object for Default Target Computer**

In this example, you create a target object that represents the default target computer.

• Create target object tg for default target computer by using configured name for default target computer. You can select the default target computer by using Simulink Real-Time Explorer.

```
tg = slrealtime
```

In this example, you create a target object that represents target computer TargetPC1.

• Create target object tg for default target computer by using explicit name for default target computer.

```
tg = slrealtime('TargetPC1')
```

### **Build and Run Real-Time Application**

Build and download slrt\_ex\_osc and execute the real-time application.

Open, build, and download the real-time application:

```
model = 'slrt_ex_osc';
open_system(model);
rtwbuild(model);
tg = slrealtime('TargetPC1');
load(tg,model);
start(tg);
```

# addInstrument

Package: slrealtime

Add instrument object to target object

# **Syntax**

```
addInstrument(target_object,instrument_object)
addInstrument(target_object,instrument_object,'updateWhileRunning')
```

# **Description**

addInstrument(target\_object,instrument\_object) adds an instrument object to the target object. Make sure that you add a signal to the instrument object before you add the instrument to the target object or no signal is streamed.

addInstrument(target\_object,instrument\_object,'updateWhileRunning') adds an instrument object to the target object and updates the target connection, even if the real-time application is running. Make sure that you add a signal to the instrument object before you add the instrument to the target object or no signal is streamed.

# **Examples**

### **Add Instrument Object**

Create a target object. Build the real-time application. Create the instrument object. Add a signal to the instrument object. Load the real-time application. Add an instrument object to the target object. Start real-time application.

```
tg = slrealtime('TargetPC1');
rtwbuild('slrt_ex_tank');
hInst = slrealtime.Instrument('slrt_ex_tank');
hInst.addSignal('slrt_ex_tank/Controller',1)
load(tg,'slrt_ex_tank');
addInstrument(tg,hInst);
start(tg);
```

# Input Arguments

### target\_object — Object that represent target computer

```
slrealtime.Target object
```

Provides access to methods that manipulate the target computer properties.

Example: tq

# instrument\_object — Object that represents real-time instrument object

To create the instrument object, use the Instrument function.

Example: hInst

# clearStartupApp

Package: slrealtime

Clear startup application selection on target computer

# **Syntax**

clearStartupApp(target object)

# **Description**

clearStartupApp(target\_object) clears the selection of the startup application on the target computer. When this selection is cleared, after booting the RTOS, the target computer waits for commands from the development computer or target computer keyboard (console).

# **Examples**

### **Clear Startup Application Selection**

This example creates a target object, connects MATLAB to the target computer, clears the startup application selection, and reboots the target computer.

```
tg = slrealtime('TargetPC1');
connect(tg);
clearStartupApp(tg);
reboot(tg);
```

# **Input Arguments**

### target object — Object that represent target computer

```
slrealtime. Target object
```

Provides access to methods that manipulate the target computer properties.

Example: tg

### See Also

Target | getStartupApp | setStartupApp

### **Topics**

"Real-Time Application and Target Computer Modes"

"Target Computer Update, Reboot, and Startup Application"

# connect

Package: slrealtime

Connect MATLAB to target computer

# **Syntax**

connect(target\_object)

# **Description**

connect (target object) connects MATLAB® to the target computer by using the target object. This connection establishes communication between the development computer and target computer.

# **Examples**

### **Connect Target Object**

Create a target object that represents the target computer. Connect the development computer and target computer by using the target object.

```
tg = slrealtime('TargetPC1');
connect(tg);
```

# **Input Arguments**

### target\_object — Object that represent target computer

slrealtime. Target object

Provides access to methods that manipulate the target computer properties.

Example: tq

### See Also

Target | load | start | stop

### **Topics**

"Real-Time Application and Target Computer Modes"

# deleteProfilerData

Package: slrealtime

Delete execution profiler data from target computer

# **Syntax**

```
deleteProfilerData(target_object,'-all')
deleteProfilerData(target_object,app_name)
```

# **Description**

deleteProfilerData(target\_object, '-all') deletes execution profiler data from all of the
installed real-time applications on the target computer.

For information about the availability of log data, see list.

deleteProfilerData(target\_object,app\_name) deletes all of the execution profiler data from the selected real-time applications on the target computer.

# **Examples**

### **Delete Profiler Data for All Applications**

For target computer object tg with execution profiler data available for real-time applications, delete profiler data for all applications.

```
deleteProfilerData(tg,'-all')
```

### **Delete Profiler Data for Selected Application**

For target computer object tg with execution profiler data available for real-time application my\_app, delete profiler data for application my\_app.

```
deleteProfilerData(tg,'my_app')
```

# **Input Arguments**

## target\_object — Object that represent target computer

```
slrealtime.Target object
```

Provides access to methods that manipulate the target computer properties.

```
Example: tq
```

### app name — Real-time application name

character vector | string scalar

Provides name of real-time application MLDATX file that you built from the model.

Example: 'slrt\_ex\_osc'

# **See Also**

Enable Profiler | ProfilerData | Target | getProfilerData | resetProfiler | startProfiler |stopProfiler

### **Topics**

"Execution Profiling for Real-Time Applications"

# disconnect

Package: slrealtime

Disconnect MATLAB from target computer

# **Syntax**

disconnect(target\_object)

# **Description**

disconnect(target\_object) disconnects MATLAB from the target computer by using the target object.

## **Examples**

## **Disconnect Target Object**

Create a target object that represents the target computer. Connect the development computer and target computer by using the target object. Disconnect the target computer.

```
tg = slrealtime('TargetPC1');
connect(tg);
disconnect(tg);
```

# **Input Arguments**

### target\_object — Object that represent target computer

slrealtime.Target object

Provides access to methods that manipulate the target computer properties.

Example: tg

### See Also

Target | load | start | stop

### **Topics**

"Real-Time Application and Target Computer Modes"

# getAvailableProfile

Package: slrealtime

Get information about available execution profiler data

# **Syntax**

```
prof_info = getAvailableProfile(target_object,app_name)
prof_info = getAvailableProfile(target_object,'-all')
```

# **Description**

prof\_info = getAvailableProfile(target\_object,app\_name) gets information about
execution profile data that is available for the specified real-time application on the target computer.

prof\_info = getAvailableProfile(target\_object,'-all') gets information about execution profile data that is available for all real-time applications on the target computer.

# **Examples**

### Get Available Profiler Data Information for Application

For target computer object tg, get information about available execution profiler data for application my\_app.

```
my_prof_info = getAvailableProfile(tg, 'my_app');
```

### **Get Available Profiler Information for All Applications**

For target computer object tg, get information about all available execution profiler data for installed applications.

```
my prof info = getAvailableProfile(tg, '-all');
```

# **Input Arguments**

### target object — Object that represent target computer

```
slrealtime. Target object
```

Provides access to methods that manipulate the target computer properties.

```
Example: tq
```

### app\_name — Real-time application name

```
character vector | string scalar
```

Provides name of real-time application MLDATX file that you built from the model.

Example: 'slrt\_ex\_osc'

# **Output Arguments**

### prof\_info — Info about application or applications with profiler data available string scalar | array of strings

If no profiler data is available, the prof\_info is an empty string. If profiler data is available for the selected real-time application, the returned string contains the application name. If profiler data is available for multiple applications and you use the '-all' option, the return value is an area of strings with each string containing an application name..

### See Also

Enable Profiler | ProfilerData | Target | deleteProfilerData | resetProfiler |
startProfiler | stopProfiler

### **Topics**

"Execution Profiling for Real-Time Applications"

# getparam

Package: slrealtime

Read value of observable parameter in real-time application

# **Syntax**

```
value = getparam(target_object, block_path, parameter_name)
value = getparam(target object, '', parameter name)
```

# **Description**

value = getparam(target object, block path, parameter name) returns the value of block parameter parameter name in block block path from the real-time application that is loaded on the target computer.

value = getparam(target\_object, '', parameter\_name) returns the value of global parameter parameter name.

# **Examples**

### Get Block Parameter by Using Parameter and Block Names

This example builds a real-time application from model slrt ex testmodel, loads the application on the target computer, and gets the value of block parameter 'Amplitude' of block 'Signal Generator'.

```
tq = slrealtime('TargetPC1');
rtwbuild('slrt ex testmodel');
load(tg,'slrt_ex_testmodel');
getparam(tg,'slrt_ex_testmodel/Signal Generator','Amplitude')
ans =
     4
```

### Get Global Parameter by Using Scalar Parameter Name

This example assumes that in model slrt ex testmodel you previously created a variable Freq and assigned the Frequency parameter value to Freq. The example builds a real-time application from model slrt ex testmodel, loads the application on the target computer, and gets the value of MATLAB variable 'Freq'.

```
tg = slrealtime('TargetPC1');
rtwbuild('slrt_ex_testmodel');
load(tg, 'slrt_ex_testmodel');
getparam(tg,'','Freq')
```

```
ans = 20
```

### **Get Global Parameter by Using Parameter Structure Name**

This example creates an array of gain values and assigns the gain parameters to its elements. The example builds a real-time application from model slrt\_ex\_testmodel, loads the application on the target computer, and gets the value of parameter structure 'oscp'.

```
oscp.G0 = 1000000;
oscp.G1 = 400;
oscp.G2 = 1000000;
set_param('slrt_ex_testmodel/Gain','Gain','oscp.G0');
set_param('slrt_ex_testmodel/Gain1','Gain','oscp.G1');
set_param('slrt_ex_testmodel/Gain2','Gain','oscp.G2');
tg = slrealtime('TargetPC1');
rtwbuild('slrt_ex_testmodel');
load(tg,'slrt_ex_testmodel');
getparam(tg,'','oscp')
ans =

G0: 1000000
G1: 400
G2: 1000000
```

# **Input Arguments**

### target object - Object that represent target computer

slrealtime. Target object

Provides access to methods that manipulate the target computer properties.

Example: tq

### block path — Hierarchical name of the originating block

character vector | string scalar | cell array of character vectors or strings

The block path values can be:

- Empty character vector ('') or empty string scalar ("") for base or model workspace variables
- Character vector or string scalar string for block path to parameters in the top model
- · Cell array of character vectors or string scalars for model block arguments

```
Example: '', 'Gain1', {'top/model', 'sub/model'}
```

### parameter\_name — Name of the parameter

character vector | string scalar

The parameter can designate either a block parameter or a global parameter that provides the value for a block parameter. The block parameter or MATLAB variable must be observable to be accessible through the parameter name.

**Note** Simulink Real-Time does not support parameters of multiword data types.

Example: 'Gain', 'oscp.G1', 'oscp', 'G2'

# **Output Arguments**

### value — Value of parameter

scalar | complex | structure

Simulink Real-Time does not support parameters of multiword data types.

# **See Also**

Target | load | setparam | start | stop

### **Topics**

"Tunable Block Parameters and Tunable Global Parameters"

"Troubleshoot Parameters Not Accessible by Name"

# getProfilerData

Package: slrealtime

Retrieve profile data object

# **Syntax**

```
profiler_object = getProfilerData(target_object)
profiler_object = getProfilerData(target_object);
```

# **Description**

profiler\_object = getProfilerData(target\_object) downloads the profiler files from the target computer to the development computer and assigns the data to the profiler\_object. It displays an execution profile plot and a code execution profiling report.

The Execution Profile plot shows the allocation of execution cycles across the four processors, indicated by the colored horizontal bars. The Code Execution Profiling Report lists the model sections. The numbers underneath the bars indicate the processor cores.

The Code Execution Profiling Report displays model execution profile results for each task.

- To display the profile data for a section of the model, click the membrane button ✓ next to the section.
- To display the TET data for the section in the Simulation Data Inspector, click the Plot time series data button ...
- To view the section in Simulink Editor, click the link next to the **Expand Tree** button [+].
- To view the lines of generated code corresponding to the section, click the expand tree button [+], and then click the view source button .

profiler\_object = getProfilerData(target\_object); downloads the profiler files from the target computer to the development computer and assigns the data to profiler\_object. To display the profiler results, call the plot and report functions with the profiler\_object as the argument.

# **Examples**

### **Run Profiler and Implicitly Display Profiler Data**

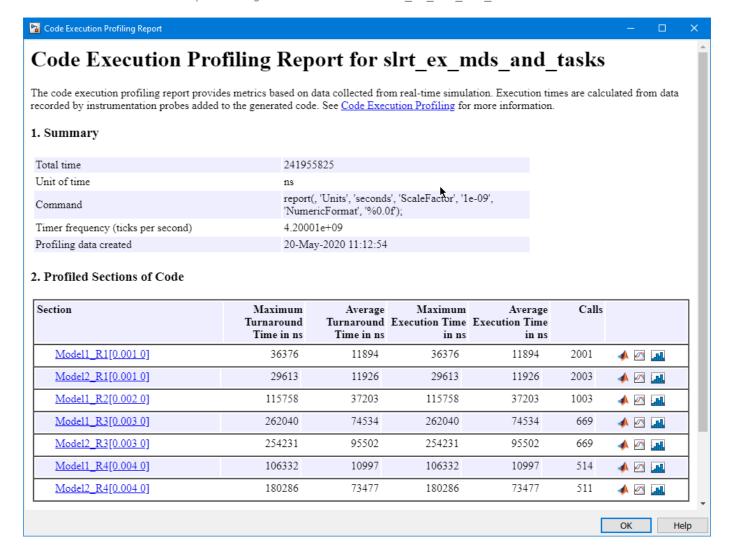

This example starts the profiler, stops the profiler, and displays execution profile data. The real-time application slrt ex mds and tasks is already loaded.

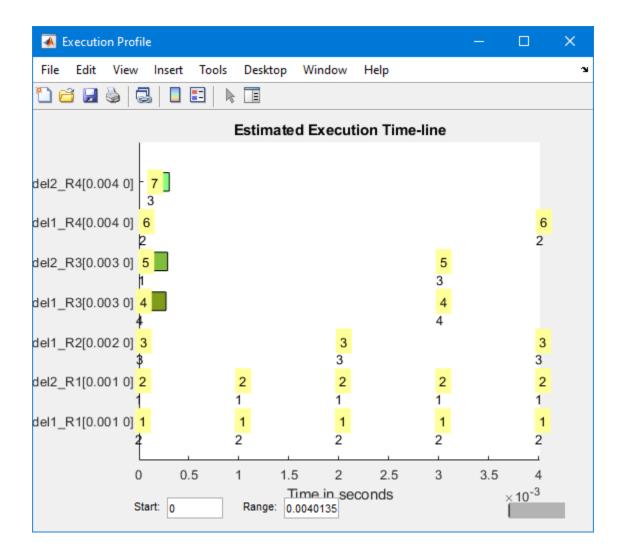

```
tg = slrealtime('TargetPC1');
rtwbuild('slrt_ex_mds_and_tasks');
load(tg,'slrt_ex_mds_and_tasks');
startProfiler(tg);
start(tg);
```

```
stopProfiler(tg);
stop(tg);
profiler_object = getProfilerData(tg)

Processing data on target computer, please wait ...
Transferring data from target computer to host computer, please wait ...
Processing data on host computer, please wait ...
```

Code execution profiling data for model slrt\_ex\_mds\_and\_tasks.

### Run Profiler and Explicitly Display Profiler Data

Starts the profiler, stops the profiler, and retrieves results data. Calls report and plot on the results data. The real-time application slrt ex mds and tasks is already loaded.

```
tg = slrealtime('TargetPC1');
rtwbuild('slrt_ex_mds_and_tasks');
load(tg,'slrt_ex_mds_and_tasks');
startProfiler(tg);
start(tg);

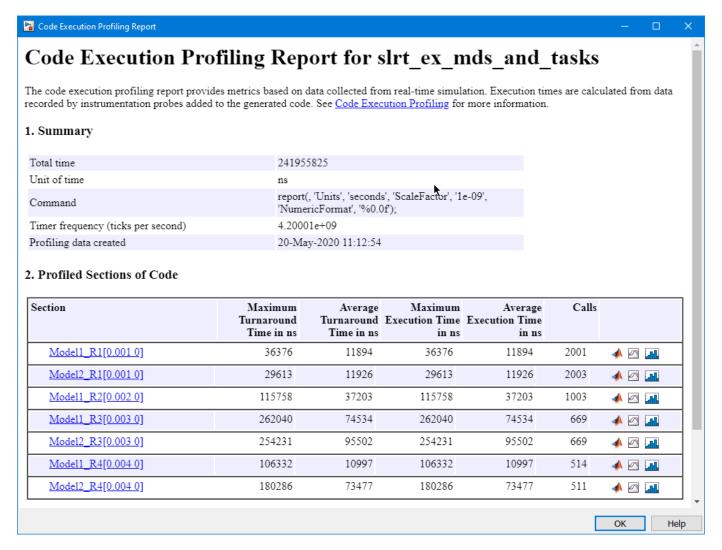

stopProfiler(tg);
stop(tg);

profiler_object = getProfilerData(tg);

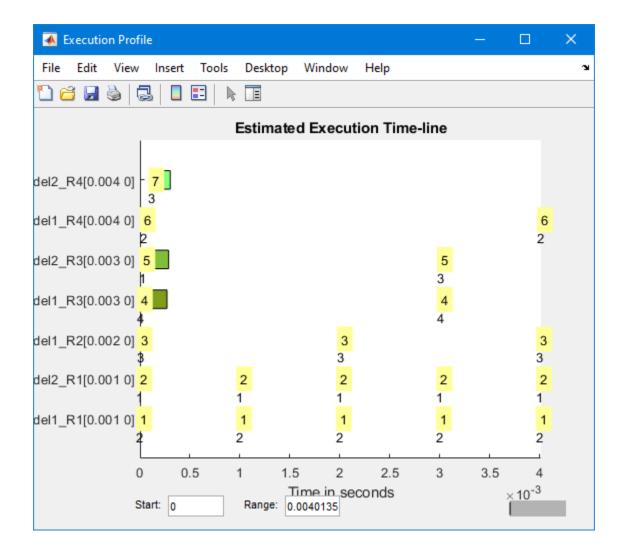

rocessing data on target computer, please wait ...
Transferring data from target computer to host computer, please wait ...
Processing data on host computer, please wait ...
```

Code execution profiling data for model slrt\_ex\_mds\_and\_tasks.

report(profiler\_object);

plot(profiler\_object);

# **Input Arguments**

### target\_object — Object that represent target computer

slrealtime.Target object

Provides access to methods that manipulate the target computer properties.

Example: tg

# **Output Arguments**

# ${\tt profiler\_object-Object\ that\ contains\ profiler\ result}$

structure

MATLAB variable that you can use to access the result of the profiler execution. You display the profiler data by calling the plot and report functions.

The structure has these fields:

- TargetName Name of target computer in target computer settings.
- ModelInfo Information about model on which profiler ran:
  - ModelName Name of real-time application.
  - MATLABRelease MATLAB release under which model was built.

You can access the data in the *profiler object* variable. To access the profiler data, before running the profiler, open the **Configuration Parameters** dialog box. In the **Real-Time** tab, click Hardware Settings. Select the Code Generation > Verification > Workspace variable option and set the value to executionProfile. Select the **Save options** option and set the value to All data. After running the profiler, use the technique described for the Sections function.

# getStartupApp

Package: slrealtime

Get information about startup application configuration on target computer

### **Syntax**

```
getStartupApp(target object)
```

### **Description**

getStartupApp(target\_object) gets information about the startup application configuration on the target computer. If you select a startup application, after booting the RTOS, the target computer loads and starts the startup application.

### **Examples**

#### **Get Startup Application for Target Object**

For target object tg, get information about the startup real-time application configuration. The getStartupApplication function returns the name of the application as a character vector.

```
tg = slrealtime('TargetPC1');
conect(tg);
load(tg,'slrt_ex_ExecutionProfAndConc')
setStartupApp(tg,'slrt_ex_ExecutionProfAndConc')
getStartupApp(tg)
ans =
   'slrt ex ExecutionProfAndConc'
```

### **Input Arguments**

#### target\_object — Object that represent target computer

```
slrealtime.Target object
```

Provides access to methods that manipulate the target computer properties.

```
Example: tg
```

#### See Also

Target | clearStartupApp | setStartupApp

#### Topics

```
"Real-Time Application and Target Computer Modes"
```

<sup>&</sup>quot;Target Computer Update, Reboot, and Startup Application"

### install

#### Package: slrealtime

Install real-time application on target computer

### **Syntax**

```
install(target_object,app_name)
install(target_object,app_name,'force')
```

### **Description**

install(target\_object,app\_name) installs a real-time application on the target computer if the
application does not exist on the target computer or if the checksum of the previously installed
application does not match the application in the install command.

install(target\_object,app\_name,'force') installs a real-time application on the target computer without checking for a previously installed application.

### **Examples**

#### **Install Application on Target Computer**

Install the real-time application slrt\_ex\_osc on the target computer TargetPC1, represented by target object tg.

```
tg = slrealtime('TargetPC1');
rtwbuild('slrt_ex_osc');
install(tg,'slrt_ex_osc');
```

#### Force Install of Application on Target Computer

Force an installation of the real-time application slrt\_ex\_osc into target computer TargetPC1, represented by target object tg. By using the force option, the function installs the real-time application on the target computer without checking for a previously installed application or checking whether a previously installed version of the application is up to date.

```
tg = slrealtime('TargetPC1');
rtwbuild('slrt_ex_osc');
install(tg,'slrt_ex_osc','force');
```

### **Input Arguments**

#### target\_object — Object that represent target computer

```
slrealtime.Target object
```

Provides access to methods that manipulate the target computer properties.

Example: tg

### app\_name — Real-time application name

character vector | string scalar

Provides name of real-time application MLDATX file that you built from the model.

Example: 'slrt\_ex\_osc'

### **See Also**

Target | start | stop

#### **Topics**

"Real-Time Application and Target Computer Modes"

### load

Package: slrealtime

Deploy to target and load real-time application to target computer

#### **Syntax**

load(target object,app name)

### Description

load(target\_object,app\_name) deploys and loads the application app\_name onto the target
computer represented by the target\_object.

The load command checks whether Simulink Real-Time software is connected to the RTOS on the target computer. If not connected, the load connects to the target computer before loading the real-time application.

You also can load the real-time application from the RTOS command line. For more information, see "Execute Target Computer RTOS Commands at Target Computer Command Line" and "Target Computer Command-Line Interface".

If you are running the real-time application in standalone mode, instead of load, consider using the install function and the setStartupApp function. For more information about Simulink Real-Time modes, see "Real-Time Application and Target Computer Modes".

### **Examples**

#### **Load Application**

Load the real-time application slrt\_ex\_osc on the target computer TargetPC1, represented by target object tg. Start the application.

Get the target object, and then build the real-time application.

```
tg = slrealtime('TargetPC1');
Build the real-time application.
rtwbuild('slrt_ex_osc');
Load the real-time application.
load(tg,'slrt_ex_osc');
```

Start the application.

start(tg);

### **Input Arguments**

### target\_object — Object that represent target computer

slrealtime. Target object

Provides access to methods that manipulate the target computer properties.

Example: tg

#### app\_name — Real-time application name

character vector | string scalar

Provides name of real-time application MLDATX file that you built from the model.

Example: 'slrt ex osc'

#### See Also

Target | start | stop

#### **Topics**

"Execute Target Computer RTOS Commands at Target Computer Command Line"

"Target Computer Command-Line Interface"

### reboot

Package: slrealtime

Restart target computer

### **Syntax**

reboot(target object)

### **Description**

reboot(target\_object) restarts the target computer that is represented by the target\_object. When you start the target computer, it boots the RTOS. The target computer boots in standalone mode. For more information, see "Real-Time Application and Target Computer Modes".

You also can reboot the target computer from the RTOS command line. For more information, see "Execute Target Computer RTOS Commands at Target Computer Command Line" and "Target Computer Command-Line Interface".

### **Examples**

#### Restart Target Computer 'TargetPC1'

Get a target object and restart the target computer that it represents.

Get target object for target computer 'TargetPC1' and connect Simulink Real-Time to the target computer.

```
tg = slrealtime('TargetPC1');
Restart target computer.
reboot(tg);
```

### **Input Arguments**

#### target object — Object that represent target computer

```
slrealtime. Target object
```

Provides access to methods that manipulate the target computer properties.

Example: tg

#### See Also

Target

### removeAllInstruments

Package: slrealtime

Remove instrument objects from target object

### **Syntax**

removeAllInstruments(target\_object)

### **Description**

removeAllInstruments(target\_object) removes the connections to instrument objects from the target object.

### **Examples**

#### **Remove Instrument Objects**

Create a target object. Build the real-time application. Create the instrument object. Add a signal to the instrument object. Load the real-time application. Add an instrument object to the target object. Start real-time application. Remove instrument objects from target object.

```
tg = slrealtime('TargetPC1');
rtwbuild('slrt_ex_tank');
hInst = slrealtime.Instrument('slrt_ex_tank');
hInst.addSignal('slrt_ex_tank/Controller',1)
load(tg,'slrt_ex_tank');
addInstrument(tg,hInst);
start(tg);
removeAllInstruments(tg);
```

### **Input Arguments**

#### target\_object - Object that represent target computer

```
slrealtime. Target object
```

Provides access to methods that manipulate the target computer properties.

Example: tg

#### See Also

### removeInstrument

Package: slrealtime

Remove selected instrument object from target object

#### **Syntax**

removeInstrument(target object,instrument object)

### **Description**

removeInstrument(target\_object,instrument\_object) removes the connection to the
selected instrument object from the target object.

### **Examples**

#### **Remove Selected Instrument Object**

Create a target object. Build the real-time application. Create the instrument object. Add a signal to the instrument object. Load the real-time application. Add an instrument object to the target object. Start real-time application. Remove the selected instrument object from target object.

```
tg = slrealtime('TargetPC1');
rtwbuild('slrt_ex_tank');
hInst = slrealtime.Instrument('slrt_ex_tank');
hInst.addSignal('slrt_ex_tank/Controller',1)
load(tg,'slrt_ex_tank');
addInstrument(tg,hInst);
start(tg);
removeInstrument(tg,hInst);
```

### **Input Arguments**

#### target\_object — Object that represent target computer

```
slrealtime.Target object
```

Provides access to methods that manipulate the target computer properties.

Example: tq

# instrument\_object — Object that represents real-time instrument object

To create the instrument object, use the Instrument function.

Example: hInst

### See Also

### resetProfiler

Package: slrealtime

Reset profiling service state to Ready

### **Syntax**

resetProfiler(target object)

### **Description**

resetProfiler(target\_object) resets the profiling service state to Ready and deletes any data that the profiler has collected.

When you start a real-time application, the profiler resets itself.

### **Examples**

#### **Reset Profiler**

Start profiling execution, and then reset the profiler. The real-time application is already running.

#### **Input Arguments**

#### target\_object — Object that represent target computer

```
slrealtime.Target object
```

Provides access to methods that manipulate the target computer properties.

```
Example: tq
```

#### See Also

Enable Profiler | ProfilerData | Target

#### **Topics**

"Execution Profiling for Real-Time Applications"

# setipaddr

Package: slrealtime

Set IP address and netmask on the target computer

### **Syntax**

```
setipaddr(target object, 'ipaddr', 'netmask')
```

### **Description**

setipaddr(target\_object,'ipaddr','netmask') sets the IP address and netmask on the
target computer. If the netmask argument is omitted, the default value is '255.255.25.0'.

### **Examples**

#### **Set IP Address on Target Computer**

For target object tg, set the target computer IP address to '10.10.10.10' and the netmask to '255.255.0'. These values are retained by the target computer.

```
tg = slrealtime('TargetPC1');
setipaddr(tg,'10.10.10.10','255.255.255.0');
reboot(tg);
```

### **Input Arguments**

#### target\_object — Object that represent target computer

```
slrealtime. Target object
```

Provides access to methods that manipulate the target computer properties.

Example: tq

#### ipaddr — IP address of target computer

character vector | string scalar

This value sets the IP address of the target computer.

```
Example: '10.10.10.10'
```

#### netmask — Netmask of target computer

```
'255.255.25.0' (default) | character vector | string scalar
```

This value sets the netmask of the target computer.

```
Example: '255.255.25'.0'
```

#### See Also

Target | load | start | stop

**Topics** "Real-Time Application and Target Computer Modes"

### setparam

Package: slrealtime

Change value of tunable parameter in real-time application

### **Syntax**

```
setparam(target_object, block_path, parameter_name, parameter_value)
setparam(target_object, '', parameter_name, parameter_value)
```

### **Description**

setparam(target\_object, block\_path, parameter\_name, parameter\_value) sets the value of a tunable block parameter to a new value. Specify the block parameter by the block name and the parameter name.

setparam(target\_object, '', parameter\_name, parameter\_value) sets the value of the tunable global parameter to a new value. Specify the global parameter by the MATLAB variable name.

#### **Examples**

#### **Set Block Parameter by Parameter and Block Names**

Set the value of the block parameter 'Amplitude' of the block 'Signal Generator' to 5.

```
tg = slrealtime('TargetPC1');
rtwbuild('slrt_ex_testmodel');
load(tg,'slrt_ex_testmodel');
setparam(tg,'slrt_ex_testmodel/Signal Generator','Amplitude',5)
```

#### **Sweep Block Parameter Values**

Sweep the value of the block parameter 'Amplitude' of the block 'Signal Generator' by steps of 2.

```
tg = slrealtime('TargetPC1');
rtwbuild('slrt_ex_testmodel');
load(tg,'slrt_ex_testmodel');
for i = 1 : 3
    setparam(tg,'slrt_ex_testmodel/Signal Generator','Amplitude',(i*2))
end
```

#### Set Global Parameter by Scalar Parameter Name

Set the value of the MATLAB variable 'Freq' to 30.

```
tg = slrealtime('TargetPC1');
rtwbuild('slrt_ex_testmodel');
load(tg,'slrt_ex_testmodel');
setparam(tg,'','Freq',30)
```

#### Set Global Parameter by Parameter Structure Field Name

Set the value of the MATLAB variable 'oscp.G2' to 10000000.

```
tg = slrealtime('TargetPC1');
rtwbuild('slrt_ex_testmodel');
load(tg,'slrt_ex_testmodel');
setparam(tg,'','oscp.G2',10000000)
```

#### **Input Arguments**

#### target\_object — Object that represent target computer

slrealtime. Target object

Provides access to methods that manipulate the target computer properties.

Example: tg

#### block\_path — Hierarchical name of the originating block

character vector | string scalar | cell array of character vectors or strings

The *block* path values can be:

- Empty character vector ('') or empty string scalar ("") for base or model workspace variables
- Character vector or string scalar string for block path to parameters in the top model
- Cell array of character vectors or string scalars for model block arguments

```
Example: '', 'Gain1', {'top/model', 'sub/model'}
```

#### parameter name — Name of the parameter

character vector | string scalar

The parameter can designate either a block parameter or a global parameter that provides the value for a block parameter. The block parameter or MATLAB variable must be observable to be accessible through the parameter name.

**Note** Simulink Real-Time does not support parameters of multiword data types.

```
Example: 'Gain', 'oscp.G1', 'oscp', 'G2'
```

#### parameter\_value — New parameter value

number | character vector | string scalar | complex | structure

New value with data type as required by parameter.

Example: 1

### **See Also**

Target | getparam | load | start | stop

"Troubleshoot Parameters Not Accessible by Name"

# **setStartupApp**

Package: slrealtime

Configure startup real-time application for target computer

### **Syntax**

```
setStartupApp(target_object,app_name)
```

### **Description**

setStartupApp(target\_object,app\_name) configures the target computer to run the selected
real-time application on startup.

### **Examples**

#### **Configure Startup Application**

Create target object, connect to target computer, and configure the startup application for the target computer. When you reboot or restart the target computer, after the target computer boots the RTOS, the startup application is loaded and runs.

```
tg = slrealtime('TargetPC1');
connect(tg);
setStartupApp(tg,'slrt_ex_osc');
```

### Input Arguments

#### target\_object — Object that represent target computer

```
slrealtime. Target object
```

Provides access to methods that manipulate the target computer properties.

Example: tq

#### app\_name — Real-time application name

```
character vector | string scalar
```

Provides name of real-time application MLDATX file that you built from the model.

```
Example: 'slrt ex osc'
```

#### See Also

Target | clearStartupApp | getStartupApp

#### **Topics**

"Real-Time Application and Target Computer Modes"

# setStopTime

Package: slrealtime

Configure stop time for real-time application

### **Syntax**

setStopTime(target\_object,stopTime)

### **Description**

setStopTime(target\_object,stopTime) configures the stop time value for the real-time
application that is loaded on the target computer. This value replaces the stop time value from the
model that built the application.

### **Examples**

#### **Configure Stop Time**

Create the target object. Load the real-time application on the target computer. Configure the stop time for the real-time application.

```
tg = slrealtime('TargetPC1');
load(tg,'slrt_ex_osc')
setStopTime(tg,10);
```

### **Input Arguments**

#### target\_object — Object that represent target computer

```
slrealtime. Target object
```

Provides access to methods that manipulate the target computer properties.

Example: tg

#### stopTime — Application stop time in seconds

double

Selects the stop time value in seconds for the real-time application. This value is a real-time application option and is retained on the target computer.

Example: 10

#### See Also

```
Target | start | stop
```

#### **Topics**

"Real-Time Application and Target Computer Modes"

### slrealtime

Package: slrealtime

Interface for managing target computer

#### **Syntax**

```
target_object = slrealtime
target object = slrealtime(target name)
```

### **Description**

target\_object = slrealtime constructs a target object representing the default target
computer. Select the default target computer by using the slrtExplorer.

target\_object = slrealtime(target\_name) constructs a target object representing the target
computer designated by target\_name.

### **Examples**

#### **Default Target Computer**

Create a target object that communicates with the default target computer. Select the default target computer by using the slrtExplorer.

```
target_object = slrealtime('TargetPC1');
```

#### **Specific Target Computer**

Create a target object that communicates with target computer TargetPC1. Report the status of the target computer. In this case, the target computer is not connected to the development computer.

```
target_object = slrealtime('TargetPC1')
Target: TargetPC1
    Connected = No
```

### **Input Arguments**

#### target\_name — Name assigned to target computer

```
character vector | string scalar
Example: 'TargetPC1'
```

Data Types: char | string

### **Output Arguments**

# $\begin{tabular}{ll} target\_object -- Object that represent target computer \\ slrealtime.Target object \end{tabular}$

Provides access to methods that manipulate the target computer properties.

Example: tg

### See Also

Target | Targets

### start

Package: slrealtime

Start execution of real-time application on target computer

### **Syntax**

start(target object,Name-Value Pair Arguments)

### **Description**

start(target\_object,Name-Value Pair Arguments) starts execution of the real-time application that is loaded on the target computer, which is represented by the target\_object. Before using this method, you must create and load the real-time application on the target computer. If a real-time application is running, issuing a start command generates an error.

You can also start the real-time application from the RTOS command line. For more information, see "Execute Target Computer RTOS Commands at Target Computer Command Line" and "Target Computer Command-Line Interface".

### **Examples**

#### Start Execution of Real-Time Application

Start execution of the real-time application that is loaded on the target computer, which is represented by the target object tq.

```
tg = slrealtime('TargetPC1');
load(tg, 'my_xpctank');
start(tg);
```

### **Input Arguments**

#### target\_object — Object that represent target computer

```
slrealtime. Target object
```

Provides access to methods that manipulate the target computer properties.

Example: tg

#### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

```
Example: start(tg, 'LogLevel', info)
```

#### LogLevel — System log message level

```
info (default) | trace | debug | warning | error | fatal
```

Selects filtering level that limits Simulink Real-Time target computer system messages that appear in the system log. For more information, see "Simulink Real-Time Options Pane".

Example: info

#### PollingThreshold — Threshold value for polling

100 (default) | int32

The real-time application is clocked by a timer interrupt, unless the base sample rate is equal to or below the polling threshold (default is  $100~\mu s$ ). If the base sample rate is less than or equal to the threshold, the real-time application is clocked in polling mode.

Example: 100

#### FileLogMaxRuns — Number of file logs retained

1 (default) | int

Select the number of file logs to retain when logs are stored on the target computer instead of uploaded to the development computer after each simulation run.

Example: 1

#### StopTime — Real-time application stop time

StopTime config set value (default)

Select stop time value for the real-time application.

Example: Inf

#### ReloadOnStop — Reload real-time application

false (default) | true

Direct Simulink Real-Time to reload the real-time application on the target computer after the application stops.

Example: false

#### AutoImportFileLog — Configure file log import

true (default) | false

Select whether the file log data is uploaded the Simulation Data Inspector on the development computer after the real-time application stops.

Example: true

#### ExportToBaseWorkspace — Configure file log export

true (default) | false

Select whether the file log data is uploaded the Simulink base workspace on the development computer after the real-time application stops

Example: true

#### See Also

Target | load | stop

### startProfiler

Package: slrealtime

Start profiling service on target computer

### **Syntax**

startProfiler(target object,app name)

### **Description**

startProfiler(target\_object,app\_name) starts the profiler on the target computer. You can start the profiler before or after you load the real-time application on the target computer. Before you start the application, you must start the profiler.

The startProfiler function affects the value of the <code>target\_object</code> property ProfilerStatus.

- Ready status indicates that the <code>target\_object</code> exists, no profiling data is available, and the <code>startProfiler</code> function has not been called.
- StartRequested status indicates that the *target\_object* exists, no profiling data is available, the startProfiler function has started the profiler, and the real-time application is not loaded.
- Running status indicates that the target\_object exists, profiling data is being collected, the startProfiler function has started the profiler, and the real-time application is loaded and running.
- DataAvailable status indicates that the *target\_object* exists, profiling data is available, and the real-time application and the profiler have stopped.

### **Examples**

#### **Profile Execution of Real-Time Application**

Build the real-time application slrt\_ex\_ExecutionProfAndConc. Load the real-time application. Start the profiler. Start the application.

```
tg = slrealtime('TargetPC1');
rtwbuild('slrt_ex_ExecutionProfAndConc');
load(tg,'slrt_ex_ExecutionProfAndConc');
startProfiler(tg);
% start profiler before starting application
start(tg);
```

#### **Check Profiler Status from Target Object Property**

Build the real-time application  $slrt_ex_ExecutionProfAndConc$ . Load the application. Check the profiler status from the target object property ProfilerStatus.

```
tg = slrealtime('TargetPC1');
rtwbuild(''slrt_ex_ExecutionProfAndConc');
load(tg,''slrt_ex_ExecutionProfAndConc');
tg.ProfilerStatus
ans =
    'Ready'
Start the profiler, and then start the application.
startProfiler(tg);
% start profiler before starting application
start(tg);
After the application stops, check the profiler status.
tg.ProfilerStatus
ans =
    'DataAvailable'
```

### **Input Arguments**

#### target object — Object that represent target computer

slrealtime.Target object

Provides access to methods that manipulate the target computer properties.

Example: tg

#### app\_name — Real-time application name

character vector | string scalar

Provides name of real-time application MLDATX file that you built from the model.

```
Example: 'slrt_ex_osc'
```

#### See Also

Enable Profiler | ProfilerData | Target | getProfilerData | resetProfiler | stopProfiler

"Execution Profiling for Real-Time Applications"

### status

Package: slrealtime

Get status of real-time application on target computer

### **Syntax**

status(target\_object)

### **Description**

status(target\_object) returns the status of the real-time application on the target computer.
The status values are:

- loading The real-time application is loading on the target computer.
- loaded The real-time application is loaded on the target computer.
- running The real-time application is running on the target computer.
- terminating The real-time application is terminating on the target computer.
- stopped The real-time application has stopped on the target computer.
- modelError An error has occurred in the real-time application on the target computer.

### **Examples**

#### **Get Application Status**

Get the status of the real-time application that is loaded on the target computer, which is represented by the target object tg.

```
tg = slrealtime('TargetPC1');
load(tg, 'my_xpctank');
status(tg);
ans =
   'loaded'
```

### **Input Arguments**

#### target\_object — Object that represent target computer

slrealtime. Target object

Provides access to methods that manipulate the target computer properties.

```
Example: tg
```

#### See Also

Target | load | start | stop

**Topics** "Real-Time Application and Target Computer Modes"

### stop

Package: slrealtime

Stop execution of real-time application on target computer

### **Syntax**

```
stop(target_object)
```

### **Description**

stop(target\_object) stops execution of the real-time application that is running on the target computer, which is represented by the target\_object. Before using this method, you must create, load, and start the real-time application on the target computer. If a real-time application is loaded on the target computer, but is not running, this command unloads the application.

You can also stop the real-time application from the RTOS command line. For more information, see "Execute Target Computer RTOS Commands at Target Computer Command Line" and "Target Computer Command-Line Interface".

### **Examples**

#### Stop Execution of Real-Time Application

Stop execution of the real-time application that is running on the target computer, which is represented by the target object tg.

```
tg = slrealtime('TargetPC1');
load(tg, 'my_xpctank');
% If stop occurs when application is loaded but not started,
% the application is unloaded (process stops).
start(tg);
stop(tg);
```

### **Input Arguments**

#### target\_object — Object that represent target computer

```
slrealtime. Target object
```

Provides access to methods that manipulate the target computer properties.

```
Example: tq
```

#### See Also

Target | load | start

# stopProfiler

Package: slrealtime

Stop profiling service on target computer

### **Syntax**

```
stopProfiler(target_object)
```

### **Description**

stopProfiler(target object) stops the profiler from running on the target computer.

If the profiler collected data, the data is available for download to the development computer.

If the profiler did not collect data, the profiler is ready to restart.

If you stop execution of the real-time application, the profiler stops.

### **Examples**

#### **Start and Stop Profiler**

Start the profiler, and then start the real-time application. After collecting execution profile data, stop the profiler.

```
tg = slrealtime('TargetPC1');
rtwbuild('slrt_ex_ExecutionProfAndConc');
load(tg,'slrt_ex_ExecutionProfAndConc');
startProfiler(tg);
% start profiler before starting application
start(tg);
% let application run until its stop time
% or stop the profiler by calling stopProfiler
stopProfiler(tg);
```

At this point, call either the getProfilerData function or the resetProfiler function.

### **Input Arguments**

### target\_object — Object that represent target computer

```
slrealtime. Target object
```

Provides access to methods that manipulate the target computer properties.

Example: tg

### **See Also**

Enable Profiler | ProfilerData | Target | getProfilerData | resetProfiler | startProfiler

"Execution Profiling for Real-Time Applications"

## update

Package: slrealtime

Update RTOS version on target computer

### **Syntax**

```
update(target_object)
update(target_object,'force',true)
```

### **Description**

update(target\_object) updates any out-of-date, not-current version RTOS files on the target computer.

update(target\_object, 'force',true) forces an update of all RTOS files on the target computer to the current version.

### **Examples**

#### **Update RTOS Version**

Create a target object that represents the target computer. Update the RTOS version on the target computer. Connect the development computer and target computer.

```
tg = slrealtime('TargetPC1');
update(tg);
connect(tq);
```

### **Force Update of RTOS Version**

Create a target object that represents the target computer. Force the update of the RTOS version on the target computer. The force option is needed for some RTOS states. Connect the development computer and target computer.

```
tg = slrealtime('TargetPC1');
update(tg,'force',true);
connect(tg);
```

### **Input Arguments**

### target\_object — Object that represent target computer

```
slrealtime. Target object
```

Provides access to methods that manipulate the target computer properties.

```
Example: tg
```

### See Also

## Target.FileLog

Target Computer file logger

## **Description**

A Target.FileLog object represents the file logger that runs on a target computer and provides access to methods and properties related to the file logger.

The object provides access to methods and properties that:

- Enable and disable the file logger.
- · Import file log data and abort import processing.
- Check for available file log data.
- Discard unwanted file log data.

Function names are case-sensitive. Type the entire name. Property names are not case-sensitive. You do not need to type the entire name if the characters you type are unique for the property.

### Creation

A Target.FileLog object is created when you create a Target object by using the slrealtime command. After you create and connect to the Target object, you can access the Target.FileLog object. This example creates and connects to Target object tg, and then starts the file logger on the target computer.

```
tg = slrealtime('TargetPC1');
connect(tg);
enable(tg.FileLog);
```

### **Properties**

#### Importing — File log import status

```
0 (not importing) (default) | 1 (importing)
```

The Importing property indicates whether the file logger is importing a file log. When FileLogger is enabled, the file logger imports file log data at the end of simulation runs. You can disable the import by setting the Disable automatic import of file logs option for the real-time application. For more information, see the start function.

Example: 0

#### ImportProgress — File log import progress percentage

```
100 (default) | 0..100 (percent complete)
```

The ImportProgress property indicates the percent completion of file log import.

Example: 100

#### LoggingService — File logging service status

STARTING (default) | RUNNING | STOPPING | STOPPED | ERROR

The LoggingService property indicates the file logging service status.

Example: 100

#### DataAvailable — File log data available status

0 (no data available) (default) | 1 (data available)

The DataAvailable property indicates whether file log data is available for import.

Example: 0

### **Object Functions**

abort Abort file log data import from target computer

disable Stop file logging of signal data

discard Delete file log data from target computer

enable Start file logging of signal data

list Get information about available file logs of signal data

import Import file log data from target computer

### **Examples**

#### **Disable File Log**

The disable function disables file logging.

Create a Target object and connect to the target computer. Creating a Target object creates a child Target.FileLog object. Connecting to the target computer provides access to the Target.FileLog object. Disable file logging.

```
tg = slrealtime('TargetPC1');
connect(tg);
disable(tg.FileLog);
```

#### See Also

Target | abort | disable | discard | enable | import | list

#### Topics

"Parameter Tuning and Data Logging"

"Signal Logging Basics"

### abort

Package: slrealtime

Abort file log data import from target computer

### **Syntax**

abort(target\_object.FileLog)

### **Description**

abort(target object.FileLog) aborts the file log import process.

If a Simulink Real-Time model has File Log blocks, when you load the real-time application, file logging is enabled. This default operation is the same as enabling file logging by using the command enable.

To control file logging by using the Enable File Log block, when you load the real-time application load, disable file logging by using the command disable.

When your development computer is connected to the target computer and the real-time application stops, the file log data is uploaded to the Simulation Data Inspector. For a standalone target computer that does file logging when not connected, after connecting the development and target computers, upload the file logging data for all available runs from an application by using the command import(Target.FileLog,'app name').

### **Examples**

#### **Abort File Log Data Import**

When you stop a real-time application that is file logging, the file log data is uploaded to the Simulation Data Inspector. You can stop the log upload, but the log data is lost. For target computer object tg that is uploading file log data from a real-time application, to stop file log import, type:

abort(tg.FileLog)

### **Input Arguments**

#### target object — Object that represent target computer

slrealtime. Target object

Provides access to methods that manipulate the target computer properties.

Example: tg

#### See Also

Enable File Log | File Log | Target | disable | discard | enable | import | list

**Topics** "Signal Logging Basics"

## disable

Package: slrealtime

Stop file logging of signal data

### **Syntax**

disable(target\_object.FileLog)

### **Description**

disable(target\_object.FileLog) stops the operation of File Log blocks that are logging signal
data.

If a Simulink Real-Time model has File Log blocks, when the real-time application is loaded, file logging is enabled. This default operation is the same as enabling file logging by using the command enable.

To control file logging by using the Enable File Log block, on real-time application load, disable file logging by using the command disable.

When the development computer is connected to the target computer and the model stops, the file log data is uploaded to the Simulation Data Inspector. For a standalone target computer that does file logging when not connected, after connecting the development and target computers, upload the file logging data for the most recent run by using the command import(Target.FileLog, 'app name').

### **Examples**

#### Disable File Logging

When you start a real-time application that has one or more File Log blocks, file logging starts. You can stop and restart file logging. For target computer object tg with a real-time application loaded and started, to stop file logging, type:

disable(tg.FileLog);

### **Input Arguments**

### target\_object — Object that represent target computer

slrealtime. Target object

Provides access to methods that manipulate the target computer properties.

Example: tg

### See Also

Enable File Log | File Log | Target | abort | discard | enable | import | list

**Topics** "Signal Logging Basics"

### enable

Package: slrealtime

Start file logging of signal data

### **Syntax**

enable(target object.FileLog)

### **Description**

enable(target object.FileLog) starts operation of stopped File Log blocks.

If a Simulink Real-Time model has File Log blocks, when the real-time application is loaded, file logging is enabled. This default operation is the same as enabling file logging by using the command enable.

To control file logging with the Enable File Log block, when the real-time application is loaded, disable file logging by using the command disable.

When the development computer is connected to the target computer and the model stops, the file log data is uploaded to the Simulation Data Inspector. For a standalone target computer that does file logging when not connected, after connecting the development and target computers, upload the file logging data for all available runs from an application by using the command import(Target.FileLog,'app name').

### **Examples**

#### **Enable File Logging**

When you start a real-time application that has one or more File Log blocks, file logging starts. You can stop and restart file logging. For target computer object tg with a real-time application loaded and started, to start file logging, type:

enable(tg.FileLog);

### **Input Arguments**

#### target object — Object that represent target computer

slrealtime. Target object

Provides access to methods that manipulate the target computer properties.

Example: tg

#### See Also

Enable File Log | File Log | Target | abort | disable | discard | import | list

**Topics** "Signal Logging Basics"

## discard

Package: slrealtime

Delete file log data from target computer

### **Syntax**

```
discard(target_object.FileLog,run_info)
discard(target_object.FileLog,app_name)
discard(target_object.FileLog,run_ids)
```

### **Description**

discard(target\_object.FileLog,run\_info) deletes file log data for the installed real-time applications on the target computer.

For information about availability of log data, see list.

discard(target\_object.FileLog,app\_name) deletes all of the file log data for the selected
real-time applications on the target computer.

discard(target\_object.FileLog,run\_ids) deletes the file log data for the simulation runs that you select from the real-time applications on the target computer.

### **Examples**

#### **Discard File Log Data for Applications**

For target computer object tg with simulation run data available for real-time applications, delete file log data for applications.

Get table of available simulation run information. Delete file log data from applications in the available file logs table.

```
my_run_info = list(tg.FileLog);
discard(tg.FileLog,my_run_info);
```

Alternatively, you can get the available file log information and delete the file log data in one step.

```
discard(tg.FileLog,tg.FileLog.list);
```

#### **Discard File Log Data for Selected Application**

For target computer object tg with simulation run data available for real-time application my\_app, delete file log data for application my\_app.

```
discard(tg.FileLog,'my_app');
```

#### **Discard File Log Data for Selected Runs**

For target computer object tg with simulation run data available for real-time applications slrt ex osc rt t and slrt ex osc, delete file log data for runs 1 and 2.

Get table of available simulation run information.

```
my_run_info = list(tg.FileLog)
my_run_info =
   3×3 table
```

	Application	StartDate	Size
1. 2.	"slrt_ex_osc_rt_t" "slrt_ex_osc_rt_t" "slrt_ex_osc"	12-Dec-2019 21:59:31 12-Dec-2019 21:59:45 12-Dec-2019 21:59:57	94944 84736 82176

Delete file log data from application runs 1 and 2 in the available file logs table.

discard(tg.FileLog,1:2);

### **Input Arguments**

## target\_object — Represent target computer object

Provides access to methods that manipulate the target computer properties.

#### app\_name — Real-time application name

character vector | string scalar

Provides name of real-time application MLDATX file that you built from the model.

```
Example: 'slrt ex osc'
```

### run\_info — Structure of information about file log runs

struct

The *run\_info* structure is a MATLAB table that is structured by Application and RowNames. For information about available log runs, see list.

#### run\_ids — Simulation run ID numbers

vector of rows in available runs table

Identifies the simulation runs to delete from the target computer. The *run\_ids* are rows in the available file logging data table. For information about available log runs, see list.

### **See Also**

Enable File Log | File Log | Target | abort | disable | enable | import | list

#### **Topics**

"Signal Logging Basics"

### list

Package: slrealtime

Get information about available file logs of signal data

### **Syntax**

```
run_info = list(target_object.FileLog)
```

### **Description**

run\_info = list(target\_object.FileLog) gets information about file log data that is
available for the real-time applications on the target computer.

When a real-time application stops on a target computer that is connected to Simulink Real-Time, the target computer uploads file log data to the development computer. If the target computer is not connected when the application stops, the file logging data for applications accumulates on the target computer. The list function returns a table that lists the accumulated file logging data for application runs.

### **Examples**

#### **Get Available File Log Information for Applications**

For target computer object tg, get information about available file log data for installed applications.

```
my_run_info = list(tg.FileLog)
my_run_info =
    3×3 table
```

	Application	StartDate	Size
1.	"slrt_ex_osc_rt_t"	12-Dec-2019 21:59:31	94944 84736
2. 3.	"slrt_ex_osc_rt_t" "slrt ex osc"	12-Dec-2019 21:59:45 12-Dec-2019 21:59:57	82176

Import file log data from application runs 1 and 2 in the available file logs table.

```
import(tg.FileLog,1:2);
```

### **Input Arguments**

### target\_object — Object that represent target computer

```
slrealtime. Target object
```

Provides access to methods that manipulate the target computer properties.

Example: tg

### **Output Arguments**

### run\_info — Structure of information about file log runs

struct

The *run\_info* structure is a MATLAB table that is structured by Application and RowNames.

### **See Also**

Enable File Log | File Log | Target | abort | disable | discard | enable | import

#### Topics

"Signal Logging Basics"

## import

Package: slrealtime

Import file log data from target computer

### **Syntax**

```
import(target_object.FileLog, 'app_name')
import(target_object.FileLog, run_info)
import(target_object.FileLog, run_ids)
```

### **Description**

import(target\_object.FileLog,'app\_name') imports file log signal data from available simulation runs for the selected real-time application.

As the function imports available file logging data, the function deletes the data from the target computer. For information about the availability of file logging data, see list.

import(target\_object.FileLog,run\_info) imports file log signal data for the selected table of available simulation runs. To create the table, use the list function.

import(target\_object.FileLog, run\_ids) imports file log signal data for the selected simulation runs.

If a Simulink Real-Time model has File Log blocks, when you load the real-time application on the target computer, file logging is enabled. This default operation is the same as enabling file logging by using the command enable.

To control file logging with the Enable File Log block, when you load the real-time application on the target computer, disable file logging by using the command disable.

When the development computer is connected to the target computer and the real-time application stops, the file log data is uploaded to the Simulation Data Inspector. For a standalone target computer that does file logging when not connected, after connecting the development and target computers, upload the file logging data for the application.

**Note:** When the Simulink Real-Time imports file log data from the target computer and uploads the data to the Simulation Data Inspector, the data is deleted from the target computer. This data is deleted whether the data upload occurs when the real-time application stops for a connected target computer or when you use the <code>import</code> function for a standalone (disconnected) target computer. File log data for imported runs of the application is deleted.

### **Examples**

### **Import File Log Data for Application**

For target computer object tg with simulation run data available for real-time application my\_app, import file log data to the Simulation Data Inspector for the application.

```
import(tg.FileLog, 'app_name')
```

#### **Import File Log Data for Applications Runs**

For target computer object tg with simulation run data available for real-time applications, get available simulation run information, and then import file log data.

Get table of available simulation run information. Import file log data from applications runs to the Simulation Data Inspector.

```
my_run_info = list(tg.FileLog);
import(tg.FileLog,my_run_info);
```

Alternatively, you can get the available file log information and import the file log data in one step.

```
import(tg.FileLog,tg.FileLog.list);
```

#### Import File Log Data for Selected Application Runs

For target computer object tg with simulation run data available for real-time applications slrt\_ex\_osc\_rt\_t and slrt\_ex\_osc, import file log data to the Simulation Data Inspector for selected simulation runs. For more information, see list.

Get table of available simulation run information.

```
my_run_info = list(tg.FileLog)
my_run_info =
    3×3 table
```

	Application	StartDate	Size
1.	"slrt_ex_osc_rt_t" "slrt_ex_osc_rt_t"	12-Dec-2019 21:59:31 12-Dec-2019 21:59:45	94944 84736
3.	"slrt_ex_osc"	12-Dec-2019 21:59:57	82176

Import file log data from application runs 1 and 2 in the available file logs table.

```
import(tg.FileLog,1:2);
```

### **Input Arguments**

### target\_object — Object that represent target computer

```
slrealtime.Target object
```

Provides access to methods that manipulate the target computer properties.

```
Example: tg
```

#### app\_name — Real-time application name

character vector | string scalar

Provides name of real-time application MLDATX file that you built from the model.

Example: 'slrt\_ex\_osc'

### run\_info — Structure of information about file log runs

struct

The *run\_info* structure is a MATLAB table that is structured by Application and RowNames. For information about available log runs, see list.

#### run\_ids — Simulation run ID numbers

vector of rows in available runs table

Identifies the simulation runs to import from the target computer into the Simulation Data Inspector. The *run\_ids* are rows in the available file logging data table. For information about available log runs, see list.

### **See Also**

## Target.ptpd

Target Computer PTP Daemon

## **Description**

A Target.ptpd object represents the RTOS PTP daemon that runs on a target computer and provides access to methods and properties related to the PTP daemon.

The object provides access to methods and properties that:

- · Start and stop the PTP daemon.
- · Configure the PTP daemon startup command.
- · Enable auto start of the PTP daemon.
- Retrieve status information about the PTP daemon.

Function names are case-sensitive. Type the entire name. Property names are not case-sensitive. You do not need to type the entire name if the characters you type are unique for the property.

### Creation

A Target.ptpd object is created when you create a Target object by using the slrealtime command. After you create and connect to the Target object, you can access the Target.ptpd object. This example creates and connects to Target object tg, and then starts the PTP daemon on the target computer.

```
tg = slrealtime('TargetPC1');
connect(tg);
start(tg.ptpd);
```

### **Properties**

### AutoStart — Enable PTP daemon start on target computer start

```
0 (off) (default) | 1 (on)
```

When AutoStart is enabled, after the target computer boots, the RTOS PTP daemon starts by using the command specified in the Target.ptpd object Command property.

Example: 0

#### Command — Specify the PTP daemon start command

```
'ptpd -L -K -g' (default) | character vector
```

The default value for the Command property is a command string that starts the RTOS PTP daemon with enable multiple daemons (-L), devctl() support (-K), and slave (-g). To change from slave to master, stop the PTP daemon, change the command string, and start the PTP daemon. To enable hardware time stamp and achieve best master-slave clock synchronization, bind the PTP daemon to an Ethernet i210 interface by using the -b switch. For more information about PTP commands, see the QNX Neutrino documentation.

```
Example: 'ptpd -L -K -g'
```

### **Object Functions**

start Start the PTP daemon on the target computer Stop the PTP daemon on the target computer stop status View the PTP daemon status on the target computer

### **Examples**

#### **Configure PTP Daemon Properties**

The Target.ptpd.Command and Target.ptpd.AutoStart properties configure operation of the PTP daemon.

Create a Target object and connect to the target computer. Creating a Target object creates a child Target.ptpd object. Connecting to the target computer provides access to the Target.ptpd object.

```
tg = slrealtime('TargetPC1');
connect(tg);
```

View the Target.ptpd object Command property value.

```
tg.ptpd.Command
ans =
    'ptpd -L -K -g'
```

View the Target.ptpd object AutoStart property value.

```
tg.ptpd.AutoStart
```

```
ans =
 logical
```

Configure Target.ptpd object Command property value for master and AutoStart property value for auto start.

```
stop(tg.ptpd); % ensure that the daemon is stopped
tg.ptpd.Command = 'ptpd -L -K -G';
tg.ptpd.AutoStart = 1:
start(tg.ptpd); % start daemon with new values
```

```

### start

Package: slrealtime

Start the PTP daemon on the target computer

### **Syntax**

```
start(target_object.ptpd)
```

### **Description**

start(target\_object.ptpd) starts the RTOS PTP daemon on the target computer

### **Examples**

#### Start PTP Daemon

The start command starts the PTP daemon on the target computer by running the command selected in the Target.ptpd object Command property value.

Create a Target object and connect to the target computer. Creating a Target object creates a child Target.ptpd object. Start the PTP daemon on the target computer.

```
tg = slrealtime('TargetPC1');
connect(tq);
start(tg.ptpd);
```

### **Input Arguments**

#### target\_object — Object that represent target computer

```
slrealtime. Target object
```

Provides access to methods that manipulate the target computer properties.

```
Example: tq
```

#### See Also

```

## stop

Package: slrealtime

Stop the PTP daemon on the target computer

### **Syntax**

```
stop(target object.ptpd)
```

### **Description**

stop(target object.ptpd) stops the RTOS PTP daemon on the target computer.

### **Examples**

### **Stop PTP Daemon**

The stop command stops the PTP daemon on the target computer.

Create a Target object and connect to the target computer. Creating a Target object creates a child Target.ptpd object. Start the PTP daemon on the target computer. Run the real-time application. Stop the PTP daemon.

```
tg = slrealtime('TargetPC1');
connect(tg);
start(tg.ptpd);
% ... run real-time application
stop(tg.ptpd);
```

### **Input Arguments**

#### target\_object — Object that represent target computer

```
slrealtime.Target object
```

Provides access to methods that manipulate the target computer properties.

```
Example: tg
```

### See Also

### status

Package: slrealtime

View the PTP daemon status on the target computer

### **Syntax**

```
status(target object.ptpd)
```

### Description

status(target object.ptpd) displays the status of the PTP daemon on the target computer.

### **Examples**

#### **View PTP Daemon Status**

The status command displays status of the PTP daemon on the target computer. This status includes PTP clock synchronization information.

Create a Target object and connect to the target computer. Creating a Target object creates a child Target.ptpd object. Start the PTP daemon on the target computer. View status of the PTP daemon.

```
tg = slrealtime('TargetPC1');
connect(tg);
start(tg.ptpd);
status(tg.ptpd)
ans =
  struct with fields:
             Running: 1
              Devctl: 1
               Error: ''
    OffsetFromMaster: 0
       MasterToSlave: 0
       SlaveToMaster: 0
         OneWayDelay: 0
        SavedOptions: [1×1 struct]
```

### **Input Arguments**

### target\_object — Object that represent target computer

```
slrealtime. Target object
```

Provides access to methods that manipulate the target computer properties.

```
Example: tg
```

### **See Also**

## **Targets**

Configure and manage target objects

## **Description**

A Targets object represents target computers that are defined on the development computer and provides access to methods related to the target computers.

### Creation

targets\_object = slrealtime.Targets() constructs a Targets object representing target
computers that are connected to the development computer.

Example: "Create Targets Object, Add Target Computers, Set IP Address" on page 1-92

### **Object Functions**

addTarget Add target computer definition to targets object
removeTarget Remove target computer definition from targets object
getTargetSettings Get target computer environment settings
getDefaultTargetName Set default target computer name
Set default target computer name

### **Examples**

#### Create Targets Object, Add Target Computers, Set IP Address

To work with multiple target computers, make the computer names available by using a targets object.

Create targets object my\_tgs. Add target computers to the targets object. Assign target computers to target objects. Create target settings object and list the target computer names.

```
my_tgs = slrealtime.Targets();
% do not need to add default target 'TargetPC1'
addTarget(my_tgs,'TargetPC2');
addTarget(my_tgs,'TargetPC3');
% assign target computers to target objects
tg1 = slrealtime('TargetPC1');
tg2 = slrealtime('TargetPC2');
tg3 = slrealtime('TargetPC3');
% list target computer names
my_tgs_settings = getTargetSettings(my_tgs);
my_tgs_settings.name
ans =
```

```
'TargetPC1'

ans =

'TargetPC2'

Set Target object tg2 IP address to '10.10.10.25' by using the targetSettings property.

tg1.targetSettings.address = '10.10.10.25';
tg1.targetSettings;
```

To set the IP address on the target computer, use the  ${\tt setipaddr}$  function.

### **See Also**

addTarget|getTargetSettings|removeTarget

## addTarget

Package: slrealtime

Add target computer definition to targets object

### **Syntax**

```
addTarget(targets_object,target_name)
```

### **Description**

addTarget(targets\_object, target\_name) adds the definition for a target computer, represented by the name target\_name. Do not add or remove the default target computer name TargetPC1.

### **Examples**

#### Add Target 'TargetPC2' to System

```
Add target computer definition 'TargetPC2' to Targets object my tgs.
```

```
my_tgs = slrealtime.Targets();
addTarget(my_tgs,'TargetPC2');
```

### **Input Arguments**

#### targets\_object — Object that represents target computers

Targets object

Provides access to methods that manipulate the target computers and their target settings.

```
Example: tgs
Data Types: struct
```

### target\_name — Name assigned to target computer

```
character vector | string scalar
Example: 'TargetPC1'
Data Types: char | string
```

#### See Also

Targets | getTargetSettings | removeTarget

## getTargetSettings

Package: slrealtime

Get target computer environment settings

### **Syntax**

```
settings_object = getTargetSettings(targets_object)
```

### **Description**

settings\_object = getTargetSettings(targets\_object) gets the environment settings for
the target computers that are connected to the development computer.

### **Examples**

#### **Create Targets Object and View Settings**

```
Create Targets object my_tgs. Get target settings for object.
```

Get target computer name properties from Targets object.

```
my_tgs_settings.name
ans =
    'TargetPC1'
ans =
    'TargetPC2'
```

Get target computer address properties from Targets object.

```
my_tgs_settings.address
```

```
ans =
    '10.10.10.15'
ans =
    '10.10.10.25'
```

To change target computer settings, use the properties of the Target object.

### **Input Arguments**

### targets\_object — Object that represents target computers

Targets object

Provides access to methods that manipulate the target computers and their target settings.

Example: tgs Data Types: struct

### **Output Arguments**

### settings\_object — Settings object that represents target computer settings

slrealtime.TargetSettings object

Object containing target computer environment settings.

Data Types: struct

#### See Also

Targets | addTarget | removeTarget

## removeTarget

Package: slrealtime

Remove target computer definition from targets object

### **Syntax**

removeTarget(targets object,target name)

### **Description**

removeTarget(targets\_object,target\_name) removes the definition and settings for the target computer represented by target\_name from the target\_object. The target objects associated with that target\_name become invalid. Do not add or remove the default target computer name TargetPC1.

### **Examples**

### Remove Target 'TargetPC2' from System

Remove target computer definition 'TargetPC2' from Targets object my tgs.

removeTarget(my\_tgs,'TargetPC2')

### **Input Arguments**

#### targets object — Object that represents target computers

Targets object

Provides access to methods that manipulate the target computers and their target settings.

Example: tgs

Data Types: struct

#### target\_name — Name assigned to target computer

character vector | string scalar

Example: 'TargetPC1'
Data Types: char | string

#### See Also

Targets | addTarget | getTargetSettings

## getDefaultTargetName

Package: slrealtime

Get default target computer name

### **Syntax**

getDefaultTargetName(targets\_object,target\_name)

### **Description**

getDefaultTargetName(targets\_object, target\_name) gets the name of the default target computer.

### **Examples**

#### **Get Default Target Computer Name**

```
Create Targets object my_tgs. Get default target computer name.
my_tgs = slrealtime.Targets();
getDefaultTargetName(my_tgs)
ans =
```

'TargetPC1'

### **Input Arguments**

### targets\_object — Object that represents target computers

Targets object

Provides access to methods that manipulate the target computers and their target settings.

```
Example: tgs
Data Types: struct
```

#### target\_name — Name assigned to target computer

```
character vector | string scalar
Example: 'TargetPC1'
Data Types: char | string
```

#### See Also

Targets | addTarget | removeTarget | setDefaultTargetName

## setDefaultTargetName

Package: slrealtime

Set default target computer name

### **Syntax**

setDefaultTargetName(targets object, target name)

### **Description**

setDefaultTargetName(targets\_object, target\_name) sets the name for the default target
computer.

### **Examples**

#### **Set Default Target Computer Name**

Create Targets object my tgs. Set default target computer name.

```
my_tgs = slrealtime.Targets();
setDefaultTargetName(my_tgs,'TargetPC1')
```

### **Input Arguments**

#### targets object — Object that represents target computers

Targets object

Provides access to methods that manipulate the target computers and their target settings.

```
Example: tgs
Data Types: struct
```

#### target name — Name assigned to target computer

```
character vector | string scalar
Example: 'TargetPC1'
Data Types: char | string
```

#### See Also

Targets | addTarget | getDefaultTargetName | removeTarget

## **Application**

Represent application files on development computer

## **Description**

An application object represents application files on the development computer. You can create application objects for real-time applications that you build from models.

An application object provides access to methods and properties that let you work with the application blocks and signals.

### Creation

app\_object = slrealtime.Application(application\_name) creates an object that you can
use to manipulate real-time application files on the development computer. You can create it only
after the real-time application has been built.

The slrealtime. Application function accepts these arguments:

• application\_name — Name of real-time application (character vector or string scalar). For example, 'slrt ex osc inport'.

This argument is the file name without the .mldatx file extension of the MLDATX file that the build produces on the development computer.

• app object — Represent real-time application files on the development computer.

This argument provides access to methods that manipulate the real-time application files.

Create an application object for real-time application slrt\_ex\_osc\_inport.

```
app_object = slrealtime.Application('slrt_ex_osc_inport');
```

**Example:** "Extract ASAP2 File" on page 1-101

**Example:** "Update Root-Level Inport Data" on page 1-102

**Example:** "Get and Set Application Options" on page 1-102

**Example:** "Get Application Signals and Parameters" on page 1-103

### **Properties**

#### ApplicationName — Name of real-time application

character vector | string scalar

This property is read-only.

Name of real-time application created when you built the application.

#### ModelName — Name of Simulink model

character vector | string scalar

This property is read-only.

Name of the Simulink model from which you build the real-time application.

#### UserData — Add user data to real-time application

```
[] (default) | character vector | numeric vector | cell array
```

You can assign arbitrary vector data to the **UserData** field. You can access this data from only the development computer.

```
Example: {'This string', 10}
```

#### Options — Real-time application options

character vector | string scalar

This property is read-only.

Use the Options property to get and set real-time application options. For a usage example, see "Get and Set Application Options" on page 1-102. The options are:

- fileLogMaxRuns selects the number of simulation runs that are stored for the real-time application when file logging is enabled.
- loglevel selects the log message level for the target computer system log. The available levels are error, warning, info, debug, and trace.
- pollingThreshold selects the sample rate below which the RTOS thread scheduler switches polling mode —instead of interrupt-driven mode— for clocking the real-time application. Polling mode can be useful for reducing sample time jitter. But, enabling this option causes the real-time application to consume a CPU core completely to clock and execute the base rate.
- stoptime selects the stop time for the real-time application.

### **Object Functions**

extractASAP2 Extract generated A2L file from real-time application file

getInformation Get real-time application information getParameters Get real-time application parameters getSignals Get real-time application signals

updateRootLevelInportData Replace external input data in real-time application with input data

### **Examples**

#### **Extract ASAP2 File**

Retrieve ASAP2 file from real-time application.

Create application object for the real-time application.

```
app obj = slrealtime.Application("myModel.mldatx");
```

Retrieve ASAP2 file from the real-time application.

```
extractASAP2(app_obj);
```

### **Update Root-Level Inport Data**

Change waveform data from square wave to sine wave.

Change inport waveform data from a square wave to sine wave.

```
waveform = sinewave;
Create an application object.
app_object = slrealtime.Application('slrt_ex_osc_inport');
Update inport data.
updateRootLevelInportData(app_object)
Download the updated inport data to the default target computer.
tg = slrealtime('TargetPC1');
```

# Get and Set Application Options

load(tg, 'slrt\_ex\_osc\_inport');

You can get and set real-time application options by using the application Options property.

Create an application object.

```
my_app = slrealtime.Application('slrt_ex_osc_inport');
```

View application options by getting the application Options property values.

Change the application stop time value option.

```
my_app.Options.set("stoptime",20);
```

Save application options to a MATLAB variable. Apply options from variable to the real-time application by using the load function.

```
my_options = my_app.Options.get;
save("my_options.mat", "my_options");
```

```
load("my_options.mat", "my_options");
my_app.Options.set(my_options);
```

#### **Get Application Signals and Parameters**

You can get real-time application signals and parameters by using the getParameters and getSignals functions.

Create an application object.

Get the application Signals values as structures in an array.

```
my_sigs = getSignals(my_app)
my_sigs =

1×9 struct array with fields:
    BlockPath
    PortIndex
    SignalLabel
```

View application signals as array elements.

```
my_sigs(1).BlockPath
ans =
    'slrt_ex_param_tuning/Gain'
```

Get the application Parameters values as structures in an array.

```
my_params = getParameters(my_app)
my_params =

1×7 struct array with fields:

BlockPath
BlockParameterName
```

View application parameters as array elements.

```
my_params(1).BlockParameterName
```

```
ans =
    'Gain'
```

## **See Also**

extractASAP2 | getInformation | getParameters | getSignals | updateRootLevelInportData

## **Topics**

"Define and Update Inport Data by Using MATLAB Language"

## extractASAP2

Extract generated A2L file from real-time application file

## **Syntax**

```
extractASAP2(app_obj)
extractASAP2(app_obj,Name,Value)
```

## **Description**

extractASAP2(app\_obj) retrieves an A2L file from a real-time application file and save the file in the working folder.

extractASAP2(app\_obj,Name,Value) specifies additional options to retrieve an A2L file by using one or more Name, Value pair arguments. For example, you can specify a location for saving the A2L file. You can provide the target IP address to update it in A2L file before saving it.

## **Examples**

#### **Extract A2L File Generated**

Retrieve the A2L file from real-time application.

```
% extract a2l file from mymodel application file
app_obj = slrealtime.Application('mymodel.mldatx')
extractASAP2(app_obj)
```

#### **Extract A2L File and Save with Custom Name**

Retrieve the A2L file from real-time application and then save the A2L file with the custom name specified.

```
% save extracted a2l file with custom name
app_obj = slrealtime.Application('mymodel.mldatx')
extractASAP2(app_obj,'FileName','MyApp')
```

#### Extract A2L File and Save in Custom Location

Retrieve the A2L file from real-time application and then save the A2L file in the specified location.

```
% save extracted a2l file in custom location
app_obj = slrealtime.Application('mymodel.mldatx')
extractASAP2(app_obj,'Folder','C:\workspace')
```

#### Extract A2L File and Update The Target IP Address

Retrieve the A2L file from real-time application and update the target IP Address.

```
% save extracted a2l file by updating IP Address
app_obj = slrealtime.Application('mymodel.mldatx')
extractASAP2(app obj, 'TargetIPAddress', '192.168.1.1')
```

## **Input Arguments**

#### app obj — Represent real-time application files on the development computer object

Provides access to methods that manipulate the real-time application files.

#### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Namel, Valuel, ..., NameN, ValueN.

```
Example: 'FileName', 'CustomName', 'Folder', 'C:\workspace'
```

#### FileName — Custom name to save the A2L file

character vector | string scalar

Save the A2L file retrieved from the real-time application with custom name specified.

```
Example: 'FileName', 'MyModel'
```

#### Folder — Folder location to save A2L file

character vector | string scalar

Full path of the folder in which to save the A2L file.

```
Example: 'Folder', 'D:\SLRT\Applications'
```

#### TargetIPAddress — Custom target IP address to be used in A2L file

character vector | string scalar

Extract the A2L file from the real-time application by updating the target IP address.

```
Example: 'TargetIPAddress', '192.168.1.1'
```

#### See Also

Application | updateRootLevelInportData

# getInformation

Package: slrealtime

Get real-time application information

## Syntax

```
info struct = getInformation(app object)
```

## **Description**

info\_struct = getInformation(app\_object) gets the application Information values as a
structure with properties. Use the getInformation function to get real-time application and model
information from the Application object.

## **Examples**

#### **Get Application Information**

You can get real-time application information by using the getInformation function.

Create an application object.

Get the application Information values as a structure with properties.

```
ModelSolverName: 'ode4'
MatlabVersion: '9.9.0.1343993 (R2020b) Prerelease'
```

View application information values as array elements.

```
my_app_info.ApplicationCreationDate
ans =
   '2020-04-21 10:29:08'
```

## **Input Arguments**

# ${\tt app\_object-Object}$ that represents real-time application files on the development computer

object

Provides access to methods that manipulate the real-time application files.

## **Output Arguments**

## info\_struct — Information values as a structure with properties

a structure with properties

The Information values are read-only. The structures in the array are:

- ApplicationName real-time application name
- ApplicationCreationDate real-time application creation date
- ApplicationLastModifiedDate real-time application modified date
- ModelName name of model from which real-time application was built
- ModelVersion model version
- ModelCreationDate model creation date
- ModelLastModifiedDate model modified date
- ModelLastModifiedBy model modified by
- ModelSolverType model solver type
- ModelSolverName model solver name
- MatlabVersion MATLAB version

# getParameters

Package: slrealtime

Get real-time application parameters

## **Syntax**

```
params_struct = getParameters(app_object)
```

## **Description**

params\_struct = getParameters(app\_object) gets the application Parameters values as structures in an array. Use the getParameters function to get tunable parameter information from the Application object.

## **Examples**

#### **Get Application Parameters**

You can get real-time application parameters by using the getParameters function.

Create an application object.

Get the application Parameters values as structures in an array.

```
my_params = getParameters(my_app)
my_params =

1×7 struct array with fields:
    BlockPath
    BlockParameterName
```

View application parameter values as array elements.

```
my params(1).BlockParameterName
```

```
ans =
    'Gain'
```

## **Input Arguments**

### app object — Object that represents real-time application files on the development computer

object

Provides access to methods that manipulate the real-time application files.

## **Output Arguments**

## params\_struct — Parameters values as structures in an array

structures in an array

The Parameters values are read-only. The structures in the array are:

- BlockPath block path of the parameter in the application
- BlockParameterName block parameter name in the application

"Add App Designer App to Inverted Pendulum Model"

# getSignals

Package: slrealtime

Get real-time application signals

## **Syntax**

```
sigs_struct = getSignals(app_object)
```

## **Description**

sigs\_struct = getSignals(app\_object) gets the application Signals values as structures in an
array. Use the getSignals function to get signal information for signals that are marked for
streaming to the Simulation Data Inspector from the Application object.

## **Examples**

#### **Get Application Signals**

You can get real-time application signals by using the getSignals function.

Create an application object.

Get the application Signals values as structures in an array.

```
my_sigs = getSignals(my_app)
my_sigs =

1×9 struct array with fields:
    BlockPath
    PortIndex
    SignalLabel
```

View application signals as array elements.

```
my_sigs(1).BlockPath
```

```
ans =
    'slrt_ex_param_tuning/Gain'
```

## **Input Arguments**

## app object — Object that represents real-time application files on the development computer

object

Provides access to methods that manipulate the real-time application files.

## **Output Arguments**

#### sigs struct — Signals values as structures in an array

structures in an array

The Signals values are read-only. The structures in the array are:

- BlockPath block path of the signal in the application
- PortIndex port index of the signal in the application
- SignalLabel label of the signal in the application

# updateRootLevelInportData

Package: slrealtime

Replace external input data in real-time application with input data

## **Syntax**

updateRootLevelInportData(app\_object)

## **Description**

updateRootLevelInportData(app\_object) replaces external input data in a real-time
application with new input data.

## **Examples**

#### **Update Inport Data with Application Object**

Create an application object for real-time application slrt\_ex\_osc\_inport. Use it to update the inport data.

Change inport waveform data from a square wave to sine wave.

```
waveform = sinewave;
Create an application object.
app_object = slrealtime.Application('slrt_ex_slrt_osc_inport');
Update inport data.
updateRootLevelInportData(app_object)
Download the updated inport data to the default target computer.
tg = slrealtime('TargetPC1');
load(tg, 'slrt_ex_osc_inport');
```

## **Input Arguments**

# $app\_object$ — Object that represents real-time application files on the development computer

object

Provides access to methods that manipulate the real-time application files.

## **SystemLog**

Get current console log from target computer

## **Description**

A SystemLog object represents the console log from the target computer at the time the object is created by using the slrealtime.SystemLog function.

## Creation

slog\_object = slrealtime.SystemLog(target\_object) creates a system log object that
contains a table of current target computer console messages in its messages property.

To view the target computer console log, you can create a SystemLog object and view its messages property or use the Simulink Real-Time system log viewer slrtLogViewer.

## **Properties**

#### messages — table of current console log messages

table of messages

The messages property value is a table of the current console log messages.

## **Object Functions**

slrtLogViewer Open Simulink Real-Time System Log Viewer tab in Simulink Real-Time Explorer to view the console log from target computer

## **Examples**

#### Create and View System Log

To work with multiple target computers, make the computer names available by using a targets object.

Create targets object my\_tgs. Add target computers to the targets object. Assign target computers to target objects. Create target settings object and list the target computer names.

```
tg = slrealtime('TargetPC1');
slog = slrealtime.SystemLog(tg);
slog.messages
ans =
   13×4 table
```

slrtLogViewer

## Instrument

Create real-time instrument object

## **Description**

An slrealtime.Instrument object streams signal data from a real-time simulation running on a target computer to a development computer.

## Creation

instrument\_object = slrealtime.Instrument('appName') creates an empty instrument
object for an existing real-time application appName.

**Example:** "Create Instrument Object for Real-Time Application" on page 1-118

instrument\_object = slrealtime.Instrument() creates an empty instrument object without
an assigned real-time application.

**Example:** "Create Instrument Object without Real-Time Application" on page 1-118

## **Properties**

#### AxesTimeSpan — Axes time span in seconds

Inf (default) | double

The AxesTimeSpan property controls the time axis (x-axis) for all axes in an App Designer UI. When set to Inf, the signal value from the real-time application running on the target computer is displayed in the axes. If you change to a value, for example 10, the time axis for all axes is set to that value, for example 10 seconds.

#### AxesTimeSpanOverrun — Axes time span overrun response

scroll (default) | wrap

The AxesTimeSpanOverrun property controls the response for axes in an App Designer UI when the data overruns the AxesTimeSpan property value. When the AxesTimeSpan property value is Inf, the AxesTimeSpanOverrun property has no effect. When the AxesTimeSpan property value is set in seconds, the time axis for all axes is set to a finite width (time range). When a signal value from the real-time application exceeds the largest time value on the x-axis, the axes can either **scroll** or **wrap**.

#### Application — Name of real-time application

character vector | string

You can set the value of the Application property to an existing real-time application when you create the Instrument object or you can set the value later. After value is written to this property, it become read-only. You can not change the Application property value directly after creating the object. The property value can only be changed after object creation by using the validate function.

## **Object Functions**

addInstrumentedSignals Find instrumented signals and add these to real-time instrument object

addSignal Add signal for streaming to be available in callback

clearScalarAndLineData Clear data from children of real-time instrument object

connectCallbackAdd callback that responds to new dataconnectLineConnect signal for streaming to axesconnectScalarAdd signal for streaming to scalar display

delete Delete real-time instrument object

generateScript Generate script that creates scalar and axes controls from signals,

scalars, and lines in real-time instrument object

getCallbackDataForSignal Get callback data for a signal in real-time instrument object

removeCallback Removed callback from real-time instrument object removeSignal Remove signal from real-time instrument object

validate Validate signals in instrument object

## **Examples**

#### Create Instrument Object for Real-Time Application

Create instrument object hInst for an existing real-time application appName.

```
appName = 'slrt_ex_tank.mldatx';
hInst = slrealtime.Instrument(appName);
```

#### **Create Instrument Object without Real-Time Application**

• Create instrument object *hInst* without assigning a real-time application. This approach is useful when building a GUI and the real-time application MLDATX file is not available.

```
hInst = slrealtime.Instrument();
```

#### **Apply Instrument Object Methods**

• This example shows how to create an Instrument object, apply Instrument object methods, and remove the object.

```
inst = slrealtime.Instrument();
inst.connectScalar(app.Numeric1, 'ScalarDouble1');
inst.connectScalar(app.Gauge1, 'ScalarDouble1');
inst.connectScalar(app.Numeric2, "ScalarDouble2");
inst.connectScalar(app.Gauge2, "ScalarDouble2");
inst.connectScalar(app.Text1, "myString", 'Callback', @(t,d)string(d));
inst.connectScalar(app.Text2, "myString", 'Callback', @(t,d)string(d), 'Decimation', 2);
inst.connectScalar(app.Lamp0, "TrafficLight", 'PropertyName', 'Visible', 'Callback', @(t,d)stringtonnectScalar(app.Lamp1, "TrafficLight", 'PropertyName', 'Visible', 'Callback', @(t,d)stringtonnectScalar(app.Lamp2, "TrafficLight", 'PropertyName', 'Visible', 'Callback',
```

```
ls2.Marker = '*';
ls2.MarkerSize = 4;
ls2.Color = 'black';
inst.connectLine(app.Axes1, "SineWave", 'ArrayIndex', 5, 'LineStyle', ls2, 'Callback', @(t,d)
inst.connectLine(app.Axes1, "SineWave");
inst.connectCallback(@(o,e)customPlot(o,e,app)); % plot sine waves added together with amplit
tg=slrealtime;
tg.addInstrument(inst);
inst.AxesTimeSpan = 10;
inst.AxesTimeSpanOverrun = 'wrap';
inst.AxesTimeSpan = Inf;
tg.removeInstrument(inst);
```

#### **Topics**

"Instrumentation Apps for Real-Time Applications"

# addInstrumentedSignals

Package: slrealtime

Find instrumented signals and add these to real-time instrument object

## **Syntax**

addInstrumentedSignals(instrument object)

## Description

addInstrumentedSignals(instrument\_object) finds real-time application signals that are marked for streaming to the Simulation Data Inspector and adds these instrumented signals to the real-time instrument object. If the instrument\_object does not have an assigned real-time application MLDATX file, the addSignal command issues an error message.

## **Examples**

#### **Add Instrumented Signals to Instrument Object**

Select real-time application file. Create instrument object. Add instrumented signals to the instrument object.

```
mldatxfile = 'slrt_ex_tank.mldatx';
hInst = slrealtime.Instrument(mldatxfile);
addInstrumentedSignals(hInst);
```

## **Input Arguments**

# instrument\_object — Object that represents real-time instrument object

To create the instrument object, use the Instrument function.

Example: hInst

#### See Also

Instrument | addSignal | clearScalarAndLineData | connectCallback | connectLine |
connectScalar | delete | generateScript | getCallbackDataForSignal | removeCallback
| removeSignal | validate

# addSignal

Package: slrealtime

Add signal for streaming to be available in callback

## **Syntax**

```
addSignal(instrument_object,blockPath,portIndex,Name,Value)
addSignal(instrument_object,signalName,Name,Value)
```

## Description

addSignal(instrument\_object,blockPath,portIndex,Name,Value) adds a signal by using the block path and the port index for streaming to make the signal available in a callback. Use this approach when you do not use the signal in a scalar displace or line plot.

addSignal(instrument\_object, signalName, Name, Value) adds a signal by using the signal name for streaming to make the signal available in a callback. Use this approach when you do not use the signal in a scalar displace or line plot.

## **Examples**

#### Add Signal by Using Block Path and Port Index

Add a signal for streaming to the real-time instrument object by using the block path and port index.

```
mldatxfile = 'slrt_ex_tank.mldatx';
hInst = slrealtime.Instrument(mldatxfile);
addSignal(hInst,'slrt ex tank/ControlValue',1);
```

#### **Add Signal by Using Signal Name**

Add a signal for streaming to the real-time instrument object by using the signal name.

```
% added signal name to model before building mldatxfile
mldatxfile = 'slrt_ex_tank.mldatx';
hInst = slrealtime.Instrument(mldatxfile);
addSignal(hInst,'ControlValueOut');
```

## **Input Arguments**

# instrument\_object — Object that represents real-time instrument object

To create the instrument object, use the Instrument function.

Example: hInst

### blockPath — Block path for block with signal connected to one of its outports

character vector

For the selected block, **gcb** returns the full block path name.

Example: slrt ex tank/ControlValue

#### portIndex — Index of block port that is connected to signal for streaming

integer

For the selected signal, the output port index and signal name are visible in the signal hierarchy available in Simulink Real-Time explorer or in the Model Data Editor.

Example: 1

#### signalName — Name of signal for streaming

character vector

For the selected signal, the port index and signal name are visible in the signal hierarchy available in Simulink Real-Time explorer or in the Model Data Editor.

Example: ControlValueOut

#### Name, Value — Name-value pairs that set properties values

name-value pair

The *Name*, *Value* pair argument selects the signal properties that are added to the instrument object <code>instrument\_object</code> and sets values for the properties.

Example: 'Decimation',2

#### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'Decimation',2

#### BusElement — Nonvirtual bus element

signal name (character vector)

Specifies a particular element of a nonvirtual bus to stream. The syntax for the BusElement value:

- Starts with the selected index for Array of Buses '(index).' or empty for scalar bus signals
- Contains the path from the first level down to the leaf element
- Separates each level of the hierarchy with a period '.'
- Has a leaf as last level
- Expresses the index for Array of Buses in the path as '(index)'

```
Example: 'BusElement','u1'
Example: 'BusElement','u4(1).b'
Example: 'BusElement','(1).a'
```

## **Decimation** — **Decimation** value

1 (default) | numeric, scalar, positive value

Specifies a decimation value for the signal.

Example: 'Decimation',2

## clearScalarAndLineData

Package: slrealtime

Clear data from children of real-time instrument object

## **Syntax**

clearScalarAndLineData(instrument object)

## Description

clearScalarAndLineData(instrument object) clears data from a real-time instrument object. For each scalar and axes control connected through connectLine or connectScalar, the clearScalarAndLineData function clears the UI control data. In a gauge for example, the Value field is reset and the needle points to 0. On axes for example, the line data is cleared and the axes are empty.

## **Examples**

#### **Clear Data from Instrument Object**

Select real-time application file. Create instrument object. Clear data from instrument object.

```
mldatxfile = 'slrt ex tank.mldatx';
hInst = slrealtime.Instrument(mldatxfile);
% . . . hInst streams data
clearScalarAndLineData(hInst);
```

## **Input Arguments**

## instrument object — Object that represents real-time instrument object

To create the instrument object, use the Instrument function.

Example: hInst

#### See Also

Instrument | addInstrumentedSignals | addSignal | connectCallback | connectLine | connectScalar | delete | generateScript | getCallbackDataForSignal | removeCallback | removeSignal | validate

## connectCallback

Package: slrealtime

Add callback that responds to new data

## **Syntax**

connectCallback(instrument object,hCallback)

## **Description**

connectCallback(instrument\_object,hCallback) adds a callback that responds to new data, which is available from the target computer. The eventData for the callback shares all the new data available from the target computer since the last time the callback was executed.

## **Examples**

#### Add Callback for Available New Data

Add a callback that responds to new data available from the target computer and stream that data to the real-time instrument object.

```
mldatxfile = 'slrt_ex_tank.mldatx';
hInst = slrealtime.Instrument(mldatxfile);
connectCallback(hInst,@my callback);
```

## **Input Arguments**

# instrument\_object — Object that represents real-time instrument object

To create the instrument object, use the Instrument function.

Example: hInst

# hCallback - MATLAB function handle evaluated when new data is available object

The callback responds to new data becoming available for streaming.

```
Example: @my callback
```

## connectLine

Package: slrealtime

Connect signal for streaming to axes

## **Syntax**

```
connectLine(instrument object,hAxis,blockPath,portIndex,Name,Value)
connectLine(instrument object,hAxis,signalName,Name,Value)
```

## Description

connectLine(instrument object, hAxis, blockPath, portIndex, Name, Value) connects a signal by using the block path and port index for streaming to axes.

connectLine(instrument object, hAxis, signalName, Name, Value) connects a signal by using a signal name for streaming to axes.

## **Examples**

#### **Connect Signal by Block Path and Port Index**

Connect a signal for streaming to the real-time instrument object and axes object by using the block path and port index.

```
mldatxfile = 'slrt_ex_tank.mldatx';
hInst = slrealtime.Instrument(mldatxfile);
connectLine(hInst,myAxis,'slrt_ex_tank/ControlValue',1);
```

#### **Connect Signal by Signal Name**

Connect a signal for streaming to the real-time instrument object and axis object by using a signal name.

```
% added signal name to model before building mldatxfile
mldatxfile = 'slrt ex tank.mldatx';
hInst = slrealtime.Instrument(mldatxfile);
connectLine(hInst,myAxis,'ControlValueOut');
```

## Input Arguments

## instrument object — Object that represents real-time instrument object

To create the instrument object, use the Instrument function.

```
Example: hInst
```

### hAxis — Handle to axis of a figure or UI figure

object

To create an axes object, use hAxis = gca or hAxis = axes ().

Example: myAxes

#### blockPath — Block path for block with signal connected to one of its outports

character vector

For the selected block, gcb returns the full block path name.

Example: slrt ex tank/ControlValue

## portIndex — Index of block port that is connected to signal for streaming

integer

For the selected signal, the output port index and signal name are visible in the signal hierarchy available in Simulink Real-Time explorer or in the Model Data Editor.

Example: 1

#### signalName — Name of signal for streaming

character vector

For the selected signal, the port index and signal name are visible in the signal hierarchy available in Simulink Real-Time explorer or in the Model Data Editor.

Example: ControlValueOut

#### Name, Value — Pair that set properties values

name-value pair

The *Name*, *Value* pair argument selects the signal properties that are added to the instrument object instrument object and sets values for the properties.

Example: 'Decimation',2

#### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'Decimation'.2

### ArrayIndex — Array index of multi-element signal

integer

Selects an element of a multi-element signal.

Example: 'ArrayIndex',5

#### **BusElement — Nonvirtual bus element**

signal name (character vector)

Specifies a particular element of a nonvirtual bus to stream. The syntax for the BusElement value:

- Starts with the selected index for Array of Buses '(index).' or empty for scalar bus signals
- Contains the path from the first level down to the leaf element
- Separates each level of the hierarchy with a period '.'
- · Has a leaf as last level
- Expresses the index for Array of Buses in the path as '(index)'

```
Example: 'BusElement', 'u1'
Example: 'BusElement', 'u4(1).b'
Example: 'BusElement','(1).a'
```

#### Callback — Function handle

function handle

Provides function handle for accepting (time,data) arguments and returning data.

```
Example: 'Callback', @(t,d)(d+app.Offset.Value)
```

#### Decimation — Decimation value

1 (default) | numeric, scalar, positive value

Specifies a decimation value for the signal.

```
Example: 'Decimation',2
```

### LineStyle — LineStyle object selection

```
'none' (default) | '-' | '--' | ':' | '-.'
```

A slrealtime.LineStyle object that customizes the line appearance. Valid values to select the object are '-', '--', ':', '-.', or 'none'.

```
Example: 'LineStyle', '-'
```

#### See Also

Instrument | addInstrumentedSignals | addSignal | clearScalarAndLineData | connectCallback | connectScalar | delete | generateScript | getCallbackDataForSignal|removeCallback|removeSignal|validate

## connectScalar

Package: slrealtime

Add signal for streaming to scalar display

## **Syntax**

```
connectScalar(instrument_object,hDisplay,blockPath,portIndex,Name,Value)
connectScalar(instrument_object,hDisplay,signalName,Name,Value)
```

## **Description**

connectScalar(instrument\_object,hDisplay,blockPath,portIndex,Name,Value) connects a signal by using the block path and port index for streaming to a scalar display as a scalar object.

connectScalar(instrument\_object, hDisplay, signalName, Name, Value) connects a signal by using a signal name for streaming to a scalar display as a scalar object.

## **Examples**

### Connect Signal by Using Block Path and Port Index

Connect a signal for streaming to the real-time instrument object and display the object by using the block path and port index.

```
mldatxfile = 'slrt_ex_tank.mldatx';
hInst = slrealtime.Instrument(mldatxfile);
connectScalar(hInst,myDisplay,'slrt_ex_tank/ControlValue',1);
```

#### **Connect Signal by Using Signal Name**

Connect a signal for streaming to the real-time instrument object and display the object by using a signal name.

```
% added signal name to model before building mldatxfile
mldatxfile = 'slrt_ex_tank.mldatx';
hInst = slrealtime.Instrument(mldatxfile);
connectScalar(hInst,myDisplay,'ControlValueOut');
```

## **Input Arguments**

# instrument\_object — Object that represents real-time instrument object

To create the instrument object, use the Instrument function.

Example: hInst

#### hDisplay — Handle to a scalar display

object

The scalar display object displays the streaming data from the instrument in an edit box, gauge, or other display. object.

Example: myGauge

#### blockPath — Block path for block with signal connected to one of its outports

character vector

For the selected block, gcb returns the full block path name.

Example: slrt\_ex\_tank/ControlValue

#### portIndex — Index of block port that is connected to signal for streaming

integer

For the selected signal, the output port index and signal name are visible in the signal hierarchy available in Simulink Real-Time explorer or in the Model Data Editor.

Example: 1

#### signalName — Name of signal for streaming

character vector

For the selected signal, the port index and signal name are visible in the signal hierarchy available in Simulink Real-Time explorer or in the Model Data Editor.

Example: ControlValueOut

#### Name, Value — Pair that set properties values

name-value pair

The Name, Value pair argument selects the signal properties that are added to the instrument object instrument\_object and sets values for the properties.

Example: 'Decimation',2

#### **Name-Value Pair Arguments**

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Example: 'Decimation',2

#### ArrayIndex — Array index of multi-element signal

integer

Selects an element of a multi-element signal.

Example: 'ArrayIndex',5

#### BusElement — Nonvirtual bus element

signal name (character vector)

Specifies a particular element of a nonvirtual bus to stream. The syntax for the BusElement value:

- Starts with the selected index for Array of Buses '(index).' or empty for scalar bus signals
- Contains the path from the first level down to the leaf element
- Separates each level of the hierarchy with a period '.'
- · Has a leaf as last level
- Expresses the index for Array of Buses in the path as '(index)'

```
Example: 'BusElement','u1'
Example: 'BusElement','u4(1).b'
Example: 'BusElement','(1).a'
```

#### **Callback — Function handle**

function handle

Provides function handle for accepting (time,data) arguments and returning data.

```
Example: 'Callback', @(t,d)(d+app.Offset.Value)
```

#### Decimation — Decimation value

1 (default) | numeric, scalar, positive value

Specifies a decimation value for the signal.

```
Example: 'Decimation',2
```

## LineStyle — LineStyle object selection

```
'none' (default) | '-' | '--' | ':' | '-.'
```

A slrealtime.LineStyle object that customizes the line appearance. Valid values to select the object are '-', '--', ':', '-.', or 'none'.

```
Example: 'LineStyle', '-'
```

removeCallback | removeSignal | validate

## delete

Package: slrealtime

Delete real-time instrument object

## **Syntax**

delete(instrument\_object)

## **Description**

delete(instrument object) deletes a real-time instrument object.

## **Examples**

#### **Delete Instrument Object**

Delete instrument object hInst. If the instrument object is streaming data from a real-time application, stop streaming and delete the instrument object.

```
% previously . . .
% . . . created a target object
% . . . loaded/started an application on target
% . . . created an instrument object
% . . . optionally streamed data by using instrument object
delete(hInst)
```

## **Input Arguments**

### instrument object — Object that represents real-time instrument object

To create the instrument object, use the Instrument function.

Example: hInst

## See Also

# generateScript

Package: slrealtime

Generate script that creates scalar and axes controls from signals, scalars, and lines in real-time instrument object

## **Syntax**

generateScript(instrument object)

## **Description**

generateScript(instrument\_object) generates an M-script that creates scalar and axes
controls from the signals, scalars, and lines in a real-time instrument object.

## **Examples**

#### **Generate Script from Instrument Object**

Select real-time application file. Create instrument object. Generate script that creates scalar and axes controls from instrument object.

```
mldatxfile = 'slrt_ex_tank.mldatx';
hInst = slrealtime.Instrument(mldatxfile);
generateScript(hInst);
```

## **Input Arguments**

## instrument\_object — Object that represents real-time instrument

object

To create the instrument object, use the Instrument function.

Example: hInst

# getCallbackDataForSignal

Package: slrealtime

Get callback data for a signal in real-time instrument object

## **Syntax**

```
[time,data] = getCallbackDataForSignal(instrument object,blockPath,portIndex,
Name, Value)
[time,data] = getCallbackDataForSignal(instrument object,signalName)
```

## Description

[time,data] = getCallbackDataForSignal(instrument object,blockPath,portIndex, Name, Value) gets callback data from the target computer for a signal by using the block path and the port index.

[time,data] = getCallbackDataForSignal(instrument object,signalName) gets callback data from the target computer for a signal by using the signal name. The eventData for the callback shares all the new data available from the target computer since the last time the callback was executed.

## **Examples**

#### Get Callback Data by Using Block Path and Port Index

Get callback data for a signal by using the block path and port index of the signal in the real-time application file.

```
mldatxfile = 'slrt ex tank.mldatx';
hInst = slrealtime.Instrument(mldatxfile);
connectCallback(hInst,@my callback);
addSignal(hInst,'slrt ex tank/ControlValue',1);
% . . . hInst streams data
[cv time,cv data] = getCallbackDataForSignal(hInst,'slrt ex tank/ControlValue',1);
```

#### Get Callback Data by Using Signal Name

Get callback data for a signal by using the signal name of the signal in the real-time application file.

```
mldatxfile = 'slrt ex tank.mldatx';
hInst = slrealtime.Instrument(mldatxfile);
connectCallback(hInst,@my callback);
addSignal(hInst, 'ControlValue');
```

```
% . . . hInst streams data
[cv_time,cv_data] = getCallbackDataForSignal(hInst,'ControlValue');
```

## **Input Arguments**

# instrument\_object — Object that represents real-time instrument object

To create the instrument object, use the Instrument function.

Example: hInst

#### blockPath — Block path for block with signal connected to one of its outports

character vector

For the selected block, gcb returns the full block path name.

Example: slrt ex tank/ControlValue

## portIndex — Index of block port that is connected to signal for streaming

integer

For the selected signal, the output port index and signal name are visible in the signal hierarchy available in Simulink Real-Time explorer or in the Model Data Editor.

Example: 1

#### signalName — Name of signal for streaming

character vector

For the selected signal, the port index and signal name are visible in the signal hierarchy available in Simulink Real-Time explorer or in the Model Data Editor.

Example: ControlValueOut

## **Output Arguments**

#### time — Time data from target computer

time data

The time value is the current time returned from the target computer.

#### data — Signal data from target computer

signal data

The data value is the current signal data returned from the target computer.

## removeCallback

Package: slrealtime

Removed callback from real-time instrument object

## **Syntax**

removeCallback(instrument object,hCallback)

## **Description**

removeCallback(instrument\_object,hCallback) removes a callback from a real-time
instrument object.

## **Examples**

#### Remove Callback Data from Instrument Object

Remove callback from instrument object.

```
mldatxfile = 'slrt_ex_tank.mldatx';
hInst = slrealtime.Instrument(mldatxfile);
connectCallback(hInst,@my_callback);
% . . . hInst streams data
removeCallback(hInst,@my_callback);
```

## **Input Arguments**

# instrument\_object — Object that represents real-time instrument object

To create the instrument object, use the Instrument function.

Example: hInst

# hCallback — MATLAB function handle evaluated when new data is available object

The callback stops responding to new data available for streaming.

```
Example: @my callback
```

## See Also

# removeSignal

Package: slrealtime

Remove signal from real-time instrument object

## **Syntax**

```
removeSignal(instrument_object,blockPath,portIndex,Name,Value)
removeSignal(instrument_object,signalName,Name,Value)
```

## **Description**

removeSignal(instrument\_object,blockPath,portIndex,Name,Value) removes a signal from a real-time instrument object by using the block path and the port index.

removeSignal(instrument\_object, signalName, Name, Value) removes a signal from a real-time instrument object.

## **Examples**

#### Remove Signal by Using Block Path and Port Index

Remove a signal from the real-time instrument object by using the block path and port index.

```
mldatxfile = 'slrt_ex_tank.mldatx';
hInst = slrealtime.Instrument(mldatxfile);
addSignal(hInst,'slrt_ex_tank/ControlValue',1);
% . . . hInst streams data
removeSignal(hInst,'slrt_ex_tank/ControlValue',1);
```

#### **Remove Signal by Using Signal Name**

Remove a signal from the real-time instrument object by using the signal name.

```
mldatxfile = 'slrt_ex_tank.mldatx';
hInst = slrealtime.Instrument(mldatxfile);
addSignal(hInst,'ControlValueOut');
% . . . hInst streams data
removeSignal(hInst,'ControlValueOut');
```

## **Input Arguments**

# instrument\_object — Object that represents real-time instrument object

To create the instrument object, use the Instrument function.

Example: hInst

## blockPath — Block path for block with signal connected to one of its outports

character vector

For the selected block, gcb returns the full block path name.

Example: slrt ex tank/ControlValue

## portIndex — Index of block port that is connected to signal for streaming

integer

For the selected signal, the output port index and signal name are visible in the signal hierarchy available in Simulink Real-Time explorer or in the Model Data Editor.

Example: 1

#### signalName — Name of signal for streaming

character vector

For the selected signal, the port index and signal name are visible in the signal hierarchy available in Simulink Real-Time explorer or in the Model Data Editor.

Example: ControlValueOut

Instrument | addInstrumentedSignals | addSignal | clearScalarAndLineData |
connectCallback | connectLine | connectScalar | delete | generateScript |
getCallbackDataForSignal | removeCallback | validate

# validate

Package: slrealtime

Validate signals in instrument object

### **Syntax**

instrument object = validate(instrument object,rtApplication)

### **Description**

instrument\_object = validate(instrument\_object,rtApplication) validates the
instrument object against the signals present in the real-time application. The validate operation
outputs the list of signals that are present in the instrument object, but are not available in the realtime application.

## **Examples**

### **Validate Instrument Object**

For input instrument object mySignals that contains named signals Integ\_out, Integ1\_out, and Integ2\_out, check whether the named signals are available in real-time application slrt\_ex\_osc. Any unavailable signals are added to the output instrument object unavailSignals.

```
unavailSignals = validate(mySignals,'slrt_ex_osc')
Integ2_out
```

# **Input Arguments**

# instrument\_object — Select instrument object

object

The input <code>instrument\_object</code> argument identifies the object to validate. To create an instrument object, use the <code>Instrument</code> function.

Example: hInst

#### rtApplication — Select real-time application for instrument

rtApplicationName

The <code>rtApplicationName</code> argument identifies the real-time application that contains the signals listed in the input instrument object. The validation identifies any signals in the input instrument object that are not available in the real-time application.

```
Example: slrt ex osc
```

# **Output Arguments**

# $\verb"instrument_object-Select" instrument object"$

slrealtime.Instrument object

The output <code>instrument\_object</code> argument identifies the object for validation information.

Example: hInst

# **ProfilerData**

Data returned from profiler

# **Description**

Internal format returned by profiler and displayed by using public functions.

The Code Execution Profiling Report displays model execution profile results by task.

- lackloss To display the profile data for a section of the model, click the membrane button lackloss next to the report section.
- To display the TET data for the section in the Simulation Data Inspector, click the plot time series data button .
- To view the section in Simulink Editor, click the link next to the expand tree button [+].
- To view the lines of generated code corresponding to the section, click the expand tree button [+], and then click the view source button .

The Execution Profile plot shows the allocation of execution cycles across the four processors, indicated by the colored horizontal bars. The Code Execution Profiling Report lists the model sections. The numbers underneath the bars indicate the processor cores.

#### Topics

"Execution Profiling for Real-Time Applications"

# plot

Package: slrealtime

Generate execution profiler plot

### **Syntax**

```
plot(profiler_object)
```

# **Description**

plot(profiler object) generates a plot from the profiler data.

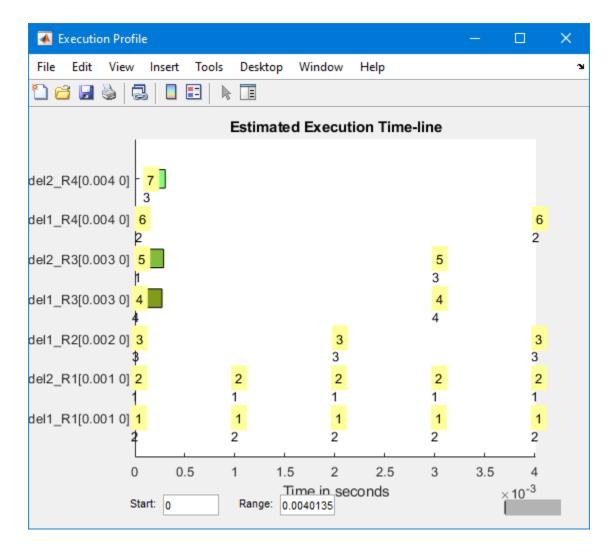

The Execution Profile plot shows the allocation of execution cycles across the four processors, indicated by the colored horizontal bars. The Code Execution Profiling Report lists the model sections. The numbers underneath the bars indicate the processor cores.

# **Examples**

#### **Run Profiler and Plot Profiler Data**

The real-time application is already loaded. Start the profiler. Start the application.

```
tg = slrealtime('TargetPC1');
startProfiler(tg);
start(tg);
Stop the profiler. Stop the application.
stopProfiler(tg);
stop(tg);
Retrieve profiler data.
profiler_object = getProfilerData(tg);
Processing data, please wait ...
Call plot function on the data.
plot(profiler_object);
```

### **Input Arguments**

# profiler\_object — Object that contains profiler result

structure

MATLAB variable that you can use to access the result of the profiler execution. You display the profiler data by calling the plot and report functions.

The structure has these fields:

- TargetName Name of target computer in target computer settings.
- ModelInfo Information about model on which profiler ran:
  - ModelName Name of real-time application.
  - MATLABRelease MATLAB release under which model was built.

You can access the data in the *profiler\_object* variable. To access the profiler data, before running the profiler, open the **Configuration Parameters** dialog box. In the **Real-Time** tab, click **Hardware Settings**. Select the **Code Generation** > **Verification** > **Workspace variable** option and

set the value to executionProfile. Select the **Save options** option and set the value to All data. After running the profiler, use the technique described for the Sections function.

# **See Also**

# report

Package: slrealtime

Generate profiler report

### **Syntax**

```
report(profiler_object)
```

### **Description**

report(profiler\_object) generates a report from the profiler data.

The **Code Execution Profiling Report** displays model execution profile results for each task.

- To display the profile data for a section of the model, click the membrane button  $\blacksquare$  next to the section.
- To display the TET data for the section in the Simulation Data Inspector, click the plot time series data button ...
- To view the section in Simulink Editor, click the link next to the expand tree button [+].
- To view the lines of generated code corresponding to the section, click the expand tree button [+], and then click the view source button .

# **Examples**

### **Run Profiler and Report Profiler Data**

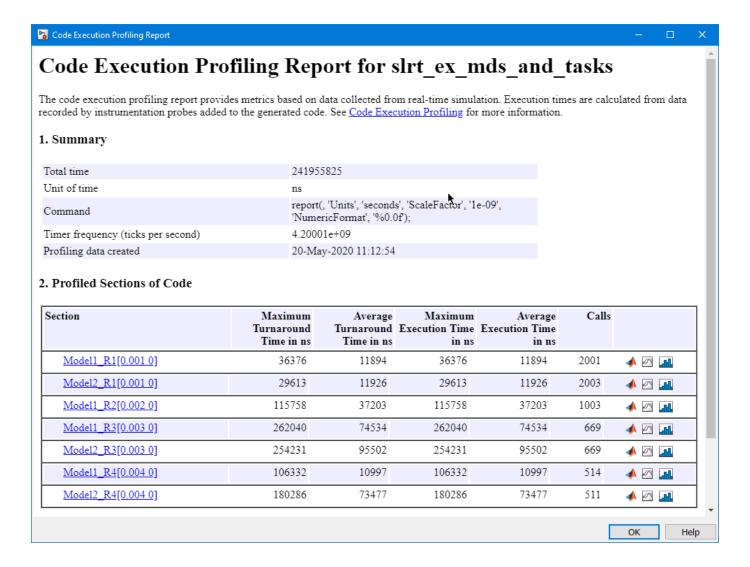

The real-time application is already loaded. Start the profiler. Start the application.

```
tg = slrealtime('TargetPC1');
startProfiler(tg);
start(tg);

Stop the profiler. Stop the application.
stopProfiler(tg);
stop(tg);

Retrieves profiler data.
profiler_object = getProfilerData(tg);
Processing data, please wait ...

Call the report function on the results data.
report(profiler_object);
```

# **Input Arguments**

### profiler\_object — Object that contains profiler result

structure

MATLAB variable that you can use to access the result of the profiler execution. You display the profiler data by calling the plot and report functions.

The structure has these fields:

- TargetName Name of target computer in target computer settings.
- ModelInfo Information about model on which profiler ran:
  - ModelName Name of real-time application.
  - MATLABRelease MATLAB release under which model was built.

You can access the data in the *profiler\_object* variable. To access the profiler data, before running the profiler, open the **Configuration Parameters** dialog box. In the **Real-Time** tab, click

**Hardware Settings**. Select the **Code Generation > Verification > Workspace variable** option and set the value to executionProfile. Select the **Save options** option and set the value to All data. After running the profiler, use the technique described for the Sections function.

# slrealtime.etherCAT.filterNotifications

Package: slrealtime

Display EtherCAT notifications in human-readable format

# **Syntax**

```
slrealtime.etherCAT.filterNotifications()
slrealtime.etherCAT.filterNotifications(tlog, olog, suppress)
filtered values = slrealtime.etherCAT.filterNotifications(tlog, olog,
suppress)
[filtered_values suppressed_values] =
slrealtime.etherCAT.filterNotifications(tlog, olog, suppress)
```

### **Description**

slrealtime.etherCAT.filterNotifications() prints the valid notification values and their text descriptions.

slrealtime.etherCAT.filterNotifications(tlog, olog, suppress) extracts from olog the notification values from the EtherCAT Get Notifications block, and from tlog, the times at which these values occurred.

If the suppress vector is nonempty, the function removes from the output list the notification values that appear in the vector. For each notification listed in the suppress vector, the function prints the total number of occurrences and the time range over which they occurred.

When you are debugging EtherCAT® issues, use this function. You must have advanced knowledge about EtherCAT functionality.

```
filtered values = slrealtime.etherCAT.filterNotifications(tlog, olog,
suppress) returns a structure vector containing the filtered values.
```

```
[filtered values suppressed values] =
slrealtime.etherCAT.filterNotifications(tlog, olog, suppress) returns a structure
vector containing the filtered values and a structure containing a summary of the suppressed values.
```

# **Examples**

#### **Print Valid Notifications**

Print the valid notification values and their text descriptions

#### **Get Time and Data Log from EtherCAT Get Notifications Block**

Export time log and data log for a simulation run from the Simulation Data Inspector. Apply the slrealtime.etherCAT.filterNotification command to the log data.

In this example, the output of the EtherCAT Get Notifications block connects to a File Log block. After the simulation run stops, Simulink Real-Time uploads the file log data to the Simulation Data Inspector. You can use the slrealtime.etherCAT.filterNotification command on the log data.

In your model, connect the output of the EtherCAT Get Notifications block connects to a File Log block.

Build the model, and then download and run the real-time application.

Open the Simulation Data Inspector.

While the real-time application is running, the Simulation Data Inspector lists any signals that are marked for logging, for example as Run 1:<modelname>@TargetPC1. When model execution stops, the Simulation Data Inspector moves that run to the archive. Then, Simulink Real-Time uploads the signal data from the File Log block to the Simulation Data Inspector. This data appears, for example as Run 2:<modelname>@TargetPC1[FileLog][Current].

To apply use the slrealtime.etherCAT.filterNotification command on the log data, export the whole data set as a single data set to the MATLAB workspace. These steps create a 1x1 data set that contains the variable notifications.

- **a** In the Simulation Data Inspector, right-click the Run 2: line.
- **b** Select **Export Data** .... That opens a dialog.
- **c** For **Export:**, select **Selected runs and signals**.
- **d** For **To:**, select **Base workspace** and provide a variable name for the export, such as notifications.

To get the timelog and the datalog use:

```
timelog = notifications{1}.Values.Time;
datalog = notifications{1}.Values.Data;
```

To print notifications from normal operations, run the filterNotifications command with this data:

slrealtime.EtherCAT.filterNotifications(timelog, datalog, [])

```
Code
                  Description
0.040000 ( 3) Scanbus finished
0.045000 (
            1) State changed
1.199000 (
             4) Distributed clocks initialized
1.202000 (
             1) State changed
             9) DCM inSync
4.198000 (
             5) DC slave synchronization deviation received
4.200000 (
4.350000 (
            1) State changed
             1) State changed
4.357000 (
```

#### **Return Filtered Notifications from Normal Operation**

Filter and return the notifications that appear during normal operation. Filter notification ( 1) State Change.

There are cases in which message filtering or suppression is useful. In certain error situations, you may see many notifications about one particular situation that can hide other significant notifications.

This situation could be a large number of working count errors or frame response errors, for example, that hide other notifications that you may need to identify how to recover from the situation.

For information about creating the timelog and datalog variables, see "Get Time and Data Log from EtherCAT Get Notifications Block" on page 1-151.

```
[filtered_values suppressed_values] = ...
    slrealtime.etherCAT.filterNotifications(timelog, datalog, [1])
                    Description
Time
           Code
              3) Scanbus finished
0.040000 (
               4) Distributed clocks initialized
1.199000 (
4.198000 (
               9) DCM inSync
4.200000 (
               5) DC slave synchronization deviation received
Suppressed notifications:
      1: 4 times [0.045000 : 4.357000]
State changed
```

### **Input Arguments**

#### tlog — Time log on target computer

vector

Use exported time log data from signal data displayed in the Simulation Data Inspector. See Get Time and Data Log from EtherCAT Get Notifications Block on page 1-151.

```
Example: timelog

Data Types: double
```

#### olog — Output log on target computer

matrix

Use exported data log data from signal data displayed in the Simulation Data Inspector. See Get Time and Data Log from EtherCAT Get Notifications Block on page 1-151.

```
Example: outputlog
Data Types: double
```

### suppress — List of notification codes to omit from line-by-line report

vector

For each code, the function reports the total number of occurrences and the time range over which they occurred. If you do not want to suppress notification codes, pass in an empty vector ([]).

```
Example: 65546
Example: []
Data Types: double
```

# **Output Arguments**

#### filtered\_values — Return filtered values as structure vector

vector

Each element of filtered\_values is a structure containing:

- time (double) Timestamp of notify code
- code (double) Notify code
- notifystring (character vector) Text description

### suppressed\_values — Return suppressed codes as structure vector

vector

Each element of suppressed\_values is a structure containing:

- val (double) Notify code
- first (double) Timestamp of first occurrence
- last (double) Timestamp of last occurrence
- count (double) Number of instances found

### **Tips**

Common error conditions, such as an unplugged Ethernet cable, can cause thousands of unwanted notifications that hide useful notifications. To filter unwanted notifications, use the suppress vector.

**EtherCAT Get Notifications** 

# slrealtime.getSupportInfo

Creates slrealtimeinfo.txt file that provides information about Simulink Real-Time installation

### **Syntax**

```
slrealtime.getSupportInfo
slrealtime.getSupportInfo(model name)
```

## **Description**

slrealtime.getSupportInfo creates an slrealtimeinfo.txt file that provides information about the Simulink Real-Time installation for MathWorks support.

slrealtime.getSupportInfo(model\_name) creates an slrealtimeinfo.txt file that provides
information about the Simulink Real-Time installation and a model\_name\_configset.m file that
provides information about the open model for MathWorks support.

## **Examples**

#### **Get Support Information for MathWorks Support**

To get support information about the Simulink Real-Time installation and a Simulink Real-Time model, open the model and run the slrealtime.getSupportInfo command.

```
open_system('slrt_ex_osc');
slrealtime.getSupportInfo('slrt_ex_osc');
```

# **Input Arguments**

### model\_name — Simulink Real-Time model name

```
character vector | string scalar
```

Provides name of Simulink Real-Time model from which you are building a real-time application.

```
Example: 'slrt ex osc'
```

#### See Also

slrealtime.getCrashStack

# slrealtime.getCrashStack

Downloads and decodes core files from target computer and opens these in MATLAB editor

### **Syntax**

```
files = slrealtime.getCrashStack(target_object)
```

### **Description**

files = slrealtime.getCrashStack(target\_object) downloads and decodes core files from the target computer and opens these in the MATLAB editor. The decoded core files help you investigate issues that cause application crashes on the target computer.

### **Examples**

#### **Get Crash Stack from Target Computer**

Create a Target object tg. Connect to the target computer. Get and open any crash stack information that is available on the target computer.

```
tg = slrealtime;
connect(tg);
my_files = slrealtime.getCrashStack(tg);
```

# **Input Arguments**

#### target object — Object that represent target computer

```
slrealtime. Target object
```

Provides access to methods that manipulate the target computer properties.

Example: tg

# **Output Arguments**

#### files — names of created crash stack files

cell array of character vectors

Holds file names created from downloaded and decoded core files.
